Academic Year 2022/2023

"If you spend more on coffee than on IT security, you will be hacked. What's more, you deserve to be hacked"

(Richard Clarke)

Abstract

This thesis focuses on enhancing the *process comprehension* of an Industrial Control System (ICS) by employing a dynamic black-box analysis approach to analyze the system's physical process. The proposed analysis methodology involves multiple steps and utilizes a custom tool capable of extracting valuable insights about the behavior of the industrial system from both physical process logs and network traffic logs. The tool and methodology will be validated through a case study based on a real-world scenario.

The ultimate goal of this analysis is to gain a deep understanding of the industrial system under examination, with the aim of uncovering as much knowledge as possible. By comprehensively studying the system's behavior and characteristics, potential attackers can develop targeted and covert attack strategies.

Introduction

1 THE advent of Industry 4.0 has sparked significant transformations in
2 T the realm of Industrial Control Systems (ICS). In recent years, there
3 has been a rapid expansion in the interconnectivity and convergence of
4 IT (*Information Technology*) and OT (*Operational Technology*) systems. While
5 this integration offers undeniable benefits in terms of operational efficiency
6 and effectiveness of ICSs, it has also exposed these systems to the preva-
7 lent vulnerabilities commonly associated with IT environments. Conse-
8 quently, there has been a parallel rise in **cyber-physical attacks**, which
9 originates in the cyber environment and target the physical processes of
10 these systems. These attacks aim to manipulate or disrupt the normal op-
11 eration of ICSs, posing a considerable risk to their integrity and function-
12 ality.

13 To execute a successful cyber-physical attack, an attacker must possess
14 a comprehensive understanding of the target system's characteristics and
15 behavior, commonly referred to as ***process comprehension***. This entails ac-
16 quiring detailed knowledge about the underlying physical processes, con-
17 trol mechanisms, communication protocols, and interdependencies within
18 the system. By attaining such insights, the attacker can effectively identify
19 vulnerabilities, exploit weaknesses, and manipulate the system in a tar-
20 geted and stealthy manner.

21 1.1 Contribution

22 The original purpose of this thesis was to validate a specific methodology
23 designed to attain *process comprehension* in an Industrial Control System
24 (ICS) when applied to a real-world scenario. This methodology, which
25 adopts a **blackbox approach**, involves dynamic analysis of the physical
26 process and network communications of the system. The primary goal
27 of this methodology is to obtain a comprehensive understanding of the
28 industrial process.

29 To accomplish this objective, a framework developed by the authors of
30 the methodology is utilized. This framework incorporates a series of analysis
31 steps that are employed to facilitate the application of the methodology.
32 The entire framework and methodology are then applied to a specially
33 implemented virtualized testbed, providing a controlled environment
34 for testing and evaluation purposes and to facilitate the process of
35 achieving process comprehension of an Industrial Control System.

36 As the thesis work advanced, it became progressively apparent that
37 both the methodology and tools employed required revision and expansion.
38 In response, an extensive revamping of the framework was conducted,
39 aimed at enhancing and expanding its existing features while introducing
40 new ones.

41 Therefore, the **primary contribution** of this thesis is to **enhance the**
42 **original methodology** by refining the existing framework, reassessing the
43 approach for each step of the analysis, and incorporating new features.
44 The objective is to achieve a more comprehensive and thorough process
45 comprehension of the industrial system under investigation. This entails
46 expanding the methodology to gather a richer set of information, improv-
47 ing the accuracy of the analysis, and incorporating additional techniques
48 to uncover hidden patterns and relationships within the system.

49 Furthermore, the enhanced methodology will be validated through the
50 application to a different and larger case study, distinct from the virtu-
51 alized testbed used previously. This real-world scenario will provide a

- 52 robust validation of the methodology's effectiveness in a practical set-
53 ting, ensuring its applicability and reliability in diverse industrial envi-
54 ronments.

55 1.2 Outline

56 The thesis is structured as follows:

- 57 **Chapter 2:** provides a background on Industrial Control Systems, (ICSSs)
58 describing their structure, components, and some of the network
59 communication protocols used;
- 60 **Chapter 3:** following an introductory section that provides a brief overview
61 of the existing literature on process comprehension in industrial con-
62 trol systems, this chapter focuses on a specific paper that outlines
63 a methodology to attaining process comprehension of an industrial
64 system by employing dynamic blackbox analysis;
- 65 **Chapter 4:** outlines a proposal to improve and extend the methodology
66 outlined in the previous chapter;
- 67 **Chapter 5:** presents the case study on which the proposed methodology
68 will be applied;
- 69 **Chapter 6:** shows how the proposed methodology is applied to the case
70 study illustrated above;
- 71 **Chapter 7:** outlines final conclusions and future work.

Background on Industrial Control Systems

⁷² INDUSTRIAL CONTROL SYSTEMS (ICSs) are information systems used to
⁷³ control industrial processes such as manufacturing, product handling,
⁷⁴ production, and distribution [1]. ICSs are often found in critical infrastruc-
⁷⁵ ture facilities such as power plants, oil and gas refineries, and chemical
⁷⁶ plant ICSs are different from traditional IT systems in several key ways.

⁷⁷ Firstly, ICSs are designed to control physical processes, whereas IT sys-
⁷⁸ tems are designed to process and store data. This means that ICSs have dif-
⁷⁹ ferent requirements for availability, reliability, and performance. Secondly,
⁸⁰ ICSs are typically deployed in environments that are harsh and have lim-
⁸¹ ited resources, such as extreme temperatures and limited power. Thirdly,
⁸² the protocols hardware and software used in ICSs are often proprietary.

⁸³ ICSs are becoming increasingly connected to the internet and other net-
⁸⁴ works, which has led to increased concerns about their security. Industrial
⁸⁵ systems were not originally designed with security in mind, and many of
⁸⁶ them have known vulnerabilities that could be exploited by attackers. Ad-
⁸⁷ ditionally, the use of legacy systems and equipment can make it difficult
⁸⁸ to implement security measures. As a result, ICSs are increasingly seen
⁸⁹ as a potential target for cyber attacks, which could have serious conse-
⁹⁰ quences for the safe and reliable operation of critical infrastructure: some
⁹¹ notorious examples of cyber attacks are (*i*) the **STUXnet** worm [2], which

purpose was to sabotage the nuclear centrifuges of the enrichment plant at the Natanz nuclear facility in Iran; (ii) **Industroyer** [3], also referred as *Crashoverride*, responsible for the attack on the Ukrainian power grid on December 17, 2016; (iii) the attack on February, 2021 to a water treatment plant in Oldsmar, Florida [4], where the level of sodium hydroxide was intentionally increased to a level approximately 100 times higher than normal.

The increasing connectivity of ICSs and the associated security risks have led to a growing interest in the field of ICS security. Researchers and practitioners are working to develop new security technologies, standards, and best practices to protect ICSs from cyber attacks. This includes efforts to improve the security of ICS networks and devices, as well as the development of new monitoring and detection techniques to identify and respond to cyber attacks.

Table 2.1 summarizes the differences between traditional IT and ICSs [5]:

| | Traditional IT | ICSs |
|----------------------------|--|--|
| Focus | Data | Asset |
| Update Frequency | High | Low |
| Priority | Confidentiality Integrity Availability | Availability Integrity Confidentiality |
| Operating System | Standardized | Proprietary |
| Protocols | Standardized | Proprietary |
| Attacker Motivation | Monetization | Disruption |

Table 2.1: differences between Information Technology (IT) and Industrial Control Systems (ICSs)

¹⁰⁹ 2.1 Industrial Control Systems Architecture

¹¹⁰ In the past, there has been a clear division between *Information Technology* (IT) and *Operational Technology* (OT), both at the technical and organizational levels. Each domain has maintained its own distinct technology stacks, protocols, and standards. However, with the emergence of Industry 4.0 and the rapid expansion of industrial automation, which heavily relies on IT tools for monitoring and controlling critical infrastructures, the boundary between IT and OT has started to blur. This trend has paved the way for greater integration between these two domains, thus improving productivity and process quality.

¹¹⁹

¹²⁰ General ICS architecture consists in **six levels** each representing a functionality: this architecture comprising the OT and IT parts is represented in Figure 2.1 [6][5], according to the *Purdue Enterprise Reference Architecture* (PERA), or simply **Purdue Model**:

¹²⁴

- Level 0 (**Processes, or Field I/O Devices**): contains **field devices**.

¹²⁵

- Level 1 (**Intelligent Devices, or Controller Network**): includes **local or remote controllers** that sense, monitor and control the physical process, such as **PLCs** (2.2.2.1) and **RTUs** (2.2.2.2). Controllers interface directly to the field devices reading data from sensors and sending commands to actuators.

¹³⁰

- Level 2 (**Control Systems, or Area Control**): contains computer systems used to supervising and monitoring the physical process: they provide a **Human-Machine Interface** (HMI, 2.2.3.2) and *Engineering Workstations* (EW) for operator control.

¹³⁴

- Level 3 (**Manufacturing/Site Operations, or Operations/Control**): comprises systems used to manage the production workflow for plant-wide control: they collate informations from the previous levels and store them in Data Historian servers.

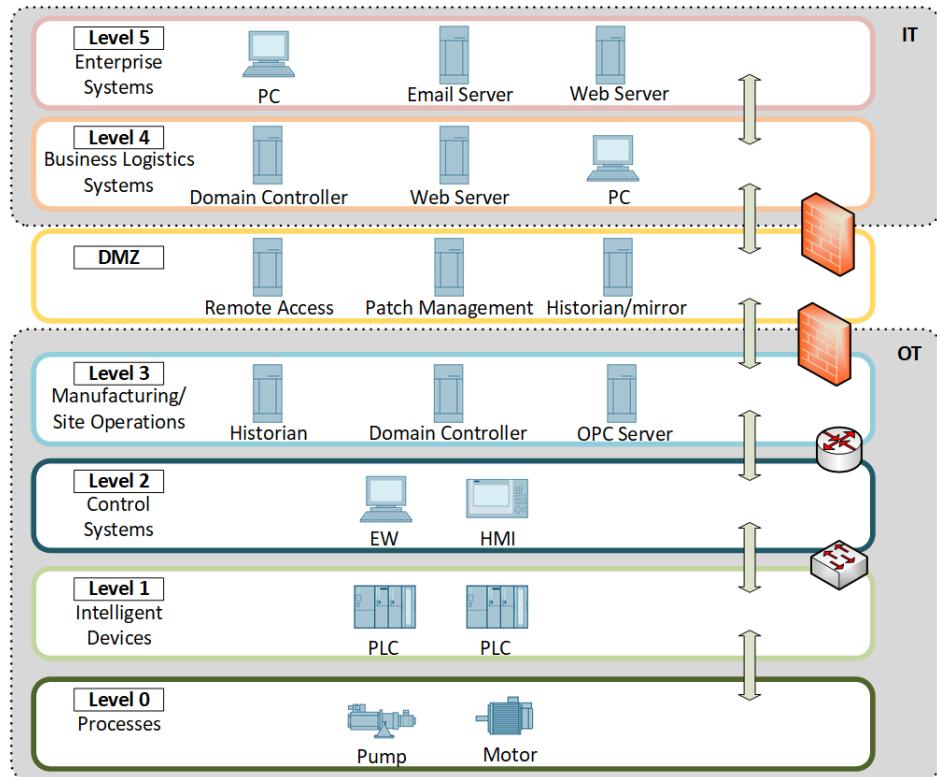

Figure 2.1: ICS architecture schema

- **Industrial Demilitarized Zone (DMZ):** intermediate level that connects the *Operational Technology* (OT) part (levels 0-3) with the *Information Technology* (IT) part of the system (levels 4 and 5). Communication takes place indirectly through services such as *proxy servers* and *remote access servers*, which act as intermediaries between the two environments.
- Level 4 (**Business Logistics Systems**, or **Business Planning/Logistics**): collect and aggregates data from the Manufacturing/Site Operations level overseeing the IT-related activities to generate **reporting** to the Enterprise System layer. At this layer we can find application and e-mail servers, and *Enterprise Resource Planning* (ERP) systems.
- Level 5 (**Enterprise Systems**): represents the enterprise network, used for the business-to-business activities and for business-to-client pur-

pose services. At Enterprise Systems level are typical IT services such as mail servers, web servers and all the systems used to manage the ongoing process.

As previously discussed, the gap between IT and OT is steadily narrowing. Nowadays, it is increasingly common to encounter IT elements within the OT realm. For example, desktop PCs are now frequently found in OT environments, and industrial devices are interconnected using standard IT communication protocols like TCP and UDP.

2.2 Operational Technology Networks

Operational Technology primarily encompasses the **tangible aspects** of Industrial Control Systems and directly interfaces with the physical processes of the monitored systems. Its main purpose is to **manage and control the procedures** involved in creating and correcting physical value in various equipment.

This section will focus on the key aspects and components of Operational Technology network, with specific reference to the first four levels of the Purdue model previously seen.

2.2.1 Field I/O Devices Layer

This level concerns all aspects related to the physical environment and the physical elements that are part of it, which have the ability to actively influence the environment.

These physical elements are represented by **Field Devices**, i.e., **sensors** and **actuators** used to collect data from the process and control it: sensors are the elements responsible for reading specific values related to the physical environment (e.g., the level of a liquid), while actuators change its behavior and characteristics (e.g., opening or closing a valve to make the liquid flow).

Examples of field devices include temperature sensors, pressure sensors, valves and pumps.

¹⁸⁰ 2.2.2 Controller Network Layer

¹⁸¹ *Controller Network* layer includes devices that handle data from and to
¹⁸² the *Field I/O Devices* layer. This kind of device is capable of gathering data
¹⁸³ from sensors, updating its internal state, and activating actuators (for ex-
¹⁸⁴ ample opening or close a pump that controls the level of a tank), making
¹⁸⁵ decisions based on a customized program, known as its control logic.
¹⁸⁶ Commonly found within this layer are *Programmable Logic Controllers* (PLCs)
¹⁸⁷ and *Remote Terminal Units* (RTUs): in the upcoming sections, we will ex-
¹⁸⁸ amine these elements in detail.

¹⁸⁹ 2.2.2.1 Programmable Logic Controllers

¹⁹⁰ A *Programmable Logic Controller* (PLC) is a **small and specialized in-**
¹⁹¹ **dustrial computer** having the capability of controlling complex industrial
¹⁹² and manufacturing processes [7].

¹⁹³ Compared to relay systems and personal computers, PLCs are opti-
¹⁹⁴ mized for control tasks and industrial environments: they are rugged and
¹⁹⁵ designed to withdraw harsh conditions such as dust, vibrations, humid-
¹⁹⁶ ity and temperature: they have more reliability than personal computers,
¹⁹⁷ which are more prone to crash, and they are more compact a require less
¹⁹⁸ maintenance than a relay system.

¹⁹⁹ Furthermore, I/O interfaces are already on the controller, so PLCs are eas-
²⁰⁰ ier to expand with additional I/O modules (if in a rack format) to manage
²⁰¹ more inputs and ouputs, without reconfiguring hardware as in relay sys-
²⁰² tems when a reconfiguration occurs.

²⁰³ PLCs are more *user-friendly*: they are not intended (only) for computer
²⁰⁴ programmers, but designed for engineers with a limited knowledge in
²⁰⁵ programming languages: control program can be entered with a simple
²⁰⁶ and intuitive language based on logic and switching operations instead of
²⁰⁷ a general-purpose programming language (*i.e.* C, C++, ...).

208 **PLC Architecture** The basic hardware architecture of a PLC consists of
209 these elements [8]:

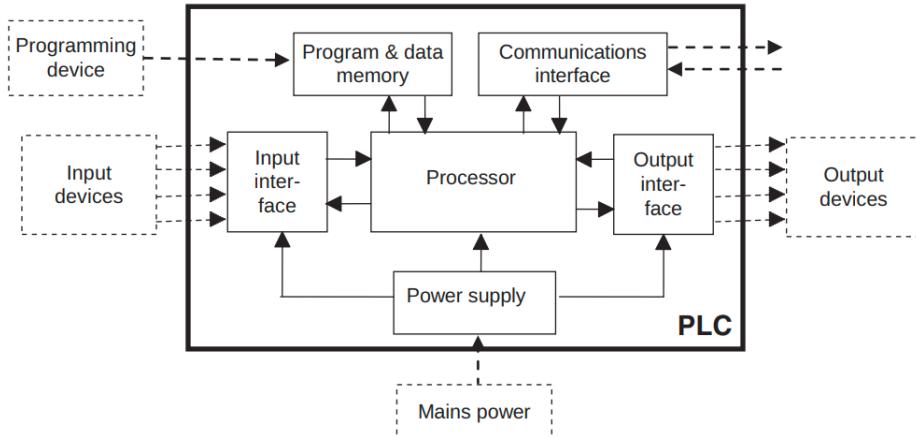

Figure 2.2: PLC architecture

- 210 • **Processor unit (CPU):** contains the microprocessor. This unit inter-
211 pretes the input signals from I/O modules, executes the control pro-
212 gram stored in the Memory Unit and sends the output signals to the
213 I/O Modules. The processor unit also sends data to the Communi-
214 cation interface, for the communication with additional devices.
- 215 • **Power supply unit:** converts AC voltage to low DC voltage.
- 216 • **Programming device:** is used to store the required program into the
217 memory unit.
- 218 • **Memory Unit:** consists in RAM memory and ROM memory. RAM
219 memory is used for storing data from inputs, ROM memory for stor-
220 ing operating system, firmware and user program to be executed by
221 the CPU.
- 222 • **I/O modules:** provide interface between sensors and final control
223 elements (actuators).
- 224 • **Communications interface:** used to send and receive data on a net-
225 work from/to other PLCs.

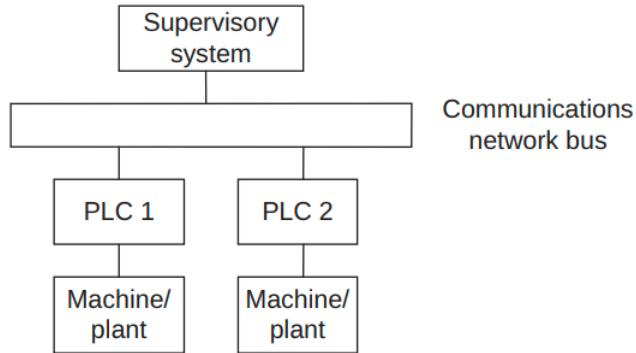

Figure 2.3: PLC communication schema

²²⁶ **PLC Programming** Two different programs are executed in a PLC: the
²²⁷ **operating system** and the **user program**.

²²⁸ The operating system tasks include executing the user program, man-
²²⁹ aging memory areas and the *process image table* (memory registers where
²³⁰ inputs from sensors and outputs for actuators are stored).

²³¹ The user program needs to be uploaded on the PLC via the program-
²³² ming device and runs on the process image table in *scan cycles*: each scan
²³³ is made up of three phases [9]:

- ²³⁴ 1. reading inputs from the process images table
- ²³⁵ 2. execution of the control code and computing the physical process evolution
- ²³⁷ 3. writing output to the process image table to have an effect on the physical process. At the end of the cycle, the process image table is refreshed by the CPU

²⁴⁰ Standard PLCs **programming languages** are basically of two types:
²⁴¹ **textuals** and **graphicals**. Textual languages include languages such as
²⁴² *Instruction List* (IL) and *Structured Text* (ST), while *Ladder Diagrams* (LD),
²⁴³ *Function Block Diagram* (FBD) and *Sequential Function Chart* (SFC) belong
²⁴⁴ to the graphical languages.

245 Graphical languages are more simple and immediate comparing to the
 246 textual ones and are preferred by programmers because of their features
 247 and simplicity, in particular the **Ladder Logic programming** (see Figure
 248 2.4 for a comparison).

```

PROGRAM PLC1

END_CONFIGURATION

```

(a) Example of ST programming

(b) Example of Ladder Logic

Figure 2.4: Comparison between ST language and Ladder Logic

249 **PLC Security** PLCs were originally designed to operate as closed sys-
 250 tems, not connected and exposed to the outside world via communication
 251 networks: the question of the safety of these systems, therefore, was not
 252 a primary aspect. The advent of Internet has brought undoubted advan-
 253 tages, but has introduced problems relating to the safety and protection of
 254 PLCs from external attacks and vulnerabilities.

255 Indeed, a variety of different communication protocols used in ICSs are
 256 designed to be efficient in communications, but do not provide any secu-
 257 rity measure i.e. confidentiality, authentication and data integrity, which
 258 makes these protocols vulnerable against many of the IT classic attacks
 259 such as *Replay Attack* or *Man in the Middle Attack*.

260 Countermeasures to enhance security in PLC systems may include [10]:

- 261 • protocol modifications implementing **data integrity, authentication**
262 and **protection** against *Replay Attacks*
- 263 • use of *Intrusion Detection and Prevention Systems* (IDP)
- 264 • creation of *Demilitarized Zones* (DMZ) on the network

265 In addition to this, keeping the process network and Internet sepa-
266 rated, limiting the use of USB devices among users to reduce the risks of
267 infections, and using strong account management and maintenance poli-
268 cies are best practices to prevent attacks and threats and to avoid potential
269 damages.

270 **2.2.2.2 Remote Terminal Units**

271 *Remote Terminal Units* (RTUs) are computers with radio interfacing sim-
272 ilar to PLCs: they transmit telemetry data to the control center or to the
273 PLCs and use messages from the master supervisory system to control
274 connected objects [11].

275 The purpose of RTUs is to operate efficiently in remote and isolated
276 locations by utilizing wireless connections. In contrast, PLCs are designed
277 for local use and rely on high-speed wired connections. This key difference
278 allows RTUs to conserve energy by operating in low-power mode for ex-
279 tended periods using batteries or solar panels. As a result, RTUs consume
280 less energy than PLCs, making them a more sustainable and cost-effective
281 option for remote operations.

282 Industries that require RTUs often operate in areas without reliable ac-
283 cess to the power grid or require monitoring and control substations in re-
284 mote locations. These include telecommunications, railways, and utilities
285 that manage critical infrastructure such as power grids, pipelines, and wa-
286 ter treatment facilities. The advanced technology of RTUs allows these in-
287 dustries to maintain essential services, even in challenging environments
288 or under adverse weather conditions.

2.2.3 Area Control Layer

The Area Control layer encompasses hardware and software systems useful for supervising, monitoring and controlling the physical process, driving the behavior of the entire infrastructure. The layer includes systems such as *Supervisory Control and Data Acquisition* (SCADA), *Distributed Control Systems* (DCSs), that perform SCADA functions but are usually deployed locally, and engineer workstations.

2.2.3.1 Supervisory Control And Data Acquisition

Supervisory Control And Data Acquisition (SCADA) is a system of software and hardware elements that allows industrial organizations to [12]:

- Control industrial processes locally or at remote locations;
- Monitor, gather, and process real-time data;
- Directly interact with devices such as sensors, valves, pumps, motors, and more through human-machine interface (HMI) software;
- Record and aggregate events to send to historian server.

The SCADA software processes, distributes, and displays the data, helping operators and other employees analyze the data and make important decisions.

2.2.3.2 Human-Machine Interface

The *Human-Machine Interface* (HMI) is the hardware and software interface that operators use to monitor the processes and interact with the ICS. A HMI shows the operator and authorized users information about system status and history; it also allows them to configure parameters on the ICS such as set points and, send commands and make control decisions [13].

The HMI can be in the form of a physical panel, with buttons and indicator lights, or PC software as shown in Figure 2.5.

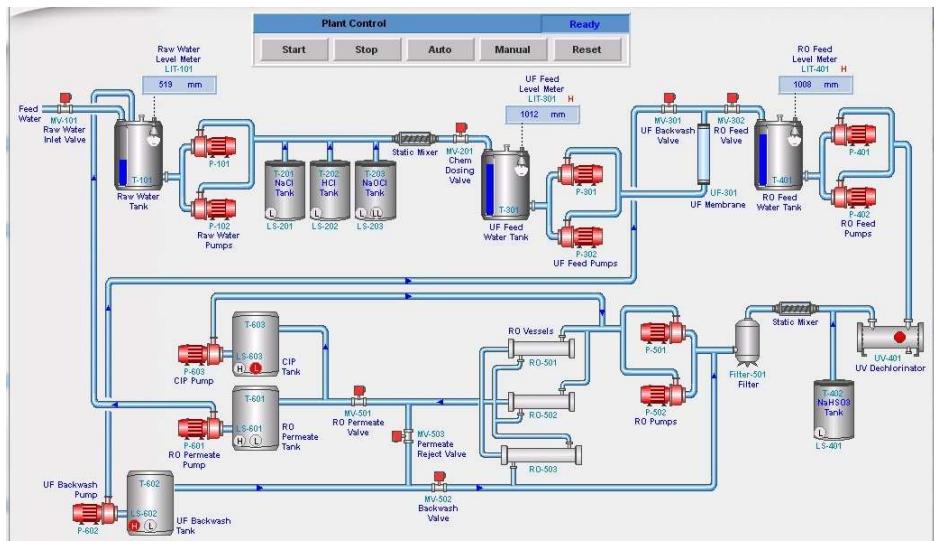

Figure 2.5: Example of HMI for a water treatment plant

316 2.2.4 Operations/Control Layer

317 Within this zone, there are specialized OT devices that are utilized to
 318 manage production workflows on the shop floor [14]. These devices in-
 319 clude:

- 320 • *Manufacturing Operations Management* (MOM) systems, which are re-
 321 sponsible for overseeing production operations.
- 322 • *Manufacturing Execution Systems* (MES), which collect real-time data
 323 to optimize production processes.
- 324 • *Data Historians*, which store process data and, in modern solutions,
 325 analyze it within its contextual framework.

326 2.2.5 Demilitarized Zone

327 This zone comprises security systems like firewalls, proxies, *Intrusion*
 328 *Detection and Prevention systems* (IDP) and *Security Information and Event*
 329 *Management* (SIEM) systems which are implemented to mitigate the risk
 330 of lateral threat movement between IT and OT domains. With the rise

331 of automation, the need for bidirectional data flows between OT and IT
332 systems has increased. The convergence of IT and OT in this layer can offer
333 organizations a competitive edge. However, it's important to note that
334 adopting a flat network approach in this context can potentially heighten
335 cyber risks for the organization.

336 2.2.6 Industrial Protocols

337 *Industrial Protocols* are the networks that are used to connect the dif-
338 ferent components of the ICS and allow them to communicate with each
339 other. Industrial Protocols can include wired and wireless networks, such
340 as Ethernet/IP, Modbus, DNP3, Profinet and others.

341 As mentioned at the beginning of this Chapter, industrial systems differ
342 from classical IT systems in the purpose for which they are designed: con-
343 trolling physical processes the former, processing and storing data the lat-
344 ter. For this reason, ICSs require different communication protocols than
345 traditional IT systems for real time communications and data transfer.

346 A wide variety of industrial protocols exists: this is because originally
347 each vendor developed and used its own proprietary protocol. How-
348 ever, these protocols were often incompatible with each other, resulting
349 in devices from different vendors being unable to communicate with each
350 other.

351 To solve this problem, standards were defined with a view to allowing
352 these otherwise incompatible device to intercommunicates.

353 Among all the various protocols, some have risen to prominence as widely
354 accepted standards. These *de facto* protocols are commonly utilized in in-
355 dustrial systems due to their proven reliability and effectiveness. In the
356 following sections, we will provide a brief overview of some of the most
357 prevalent and widely used protocols in the industry.

³⁵⁸ **2.2.6.1 Modbus**

³⁵⁹ *Modbus* is a serial communication protocol developed by Modicon (now
³⁶⁰ Schneider Electric) in 1979 for use with its PLCs [15] and designed ex-
³⁶¹ pressly for industrial use: it facilitates interoperability of different devices
³⁶² connected to the same network (sensors, PLCs, HMIs, ...) and it is also
³⁶³ often used to connect RTUs to SCADA acquisition systems.

³⁶⁴ Modbus is the most widely used communication protocol among in-
³⁶⁵ dustrial systems because it has several advantages:

- ³⁶⁶ • simplicity of implementation and debugging
- ³⁶⁷ • it moves raw bits and words, letting the individual vendor to repre-
³⁶⁸ sent the data as it prefers
- ³⁶⁹ • it is, nowadays, an **open** and *royalty-free* protocol: there is no need
³⁷⁰ to sustain licensing costs for implementation and use by industrial
³⁷¹ device vendors

³⁷² Modbus is a **request/response** (or *master/slave*) protocol: this makes it
³⁷³ independent of the transport layer used.

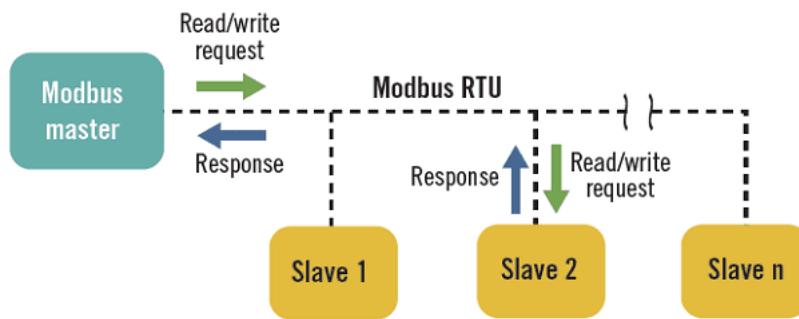

Figure 2.6: Modbus Request/Response schema

³⁷⁴ In this kind of architecture, a single device (master) can send requests
³⁷⁵ to other devices (slaves), either individually or in broadcast: these slave
³⁷⁶ devices (usually peripherals such as actuators) will respond to the master

377 by providing data or performing the action requested by the master using
378 the Modbus protocol. Slave devices cannot generate requests to the master
379 [16].

380 There are several variants of Modbus, of which the most popular and
381 widely used are Modbus RTU (used in serial port connections) and Mod-
382 bus TCP (which instead uses TCP/IP as the transport layer). Modbus TCP
383 embeds a standard Modbus frame in a TCP frame (see Figure 2.7): both
384 masters and slaves listen and receive data via TCP port 502.

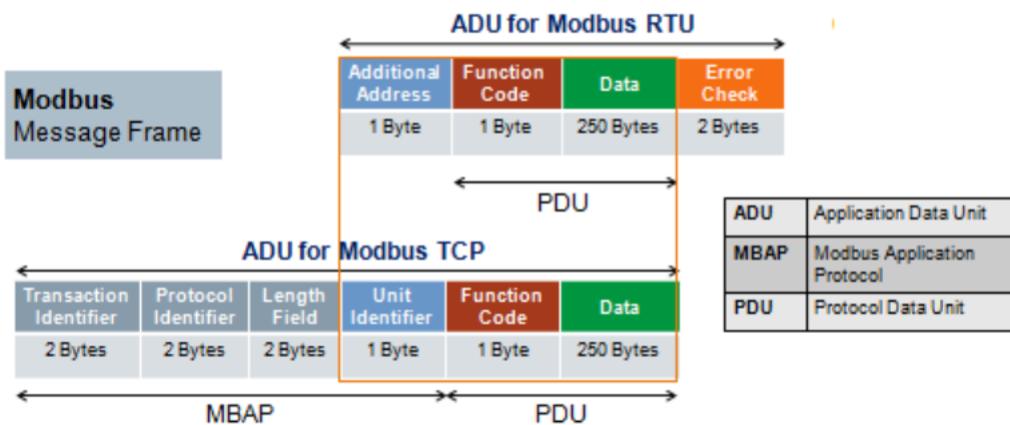

Figure 2.7: Modbus RTU frame and Modbus TCP frame

385 **Modbus registers** Modbus provides four object types, which map the
386 data accessed by master and slave to the PLC memory:

- 387 • *Coil*: binary type, read/write accessible by both masters and slaves
- 388 • *Discrete Input*: binary type, accessible in read-only mode by masters
389 and in read/write mode by slaves
- 390 • *Analog Input*: 16 bits in size (word), are accessible in read-only mode
391 by masters and in read/write mode by slaves
- 392 • *Holding Register*: 16 bits in size (word), accessible in read/write mode
393 by both masters and slaves. Holding Registers are the most com-
394 monly used registers for output and as general memory registers.

³⁹⁵ **Modbus Function Codes** *Modbus Function Codes* are specific codes used
³⁹⁶ by the Modbus master within a request frame (see Figure 2.7) to tell the
³⁹⁷ Modbus slave device which register type to access and which action to
³⁹⁸ perform on it.

³⁹⁹ Two types of Function Codes exists: for data access and for diagnostic
⁴⁰⁰ Function Codes list for data access are listed in Table 2.2:

| Function Code | Description |
|---------------|--|
| FC01 | Read Coils |
| FC02 | Read Discrete Input |
| FC03 | Read Holding Registers |
| FC04 | Read Analog Input Registers |
| FC05 | Write/Force Single Coil |
| FC06 | Write/Force Single Holding Register |
| FC15 | Write/Force Multiple Coils |
| FC16 | Write/Force Multiple Holding Registers |

Table 2.2: Modbus Function Codes list

⁴⁰¹ **Modbus Security Issues** Despite its simplicity and widespread use, the
⁴⁰² Modbus protocol does not have any security feature, which exposes it to
⁴⁰³ vulnerabilities and attacks.

⁴⁰⁴ Data in Modbus are transmitted unencrypted (*lack of confidentiality*), with
⁴⁰⁵ no data integrity controls (*lack of integrity*) and authentication checks (*lack*
⁴⁰⁶ *of authentication*), in addition to the *lack of session*. Hence, the protocol is
⁴⁰⁷ vulnerable to a variety of attacks, such as Denial of Services (DoS), buffer
⁴⁰⁸ overflows and reconnaissance activities.

⁴⁰⁹ The easiest attack to bring to the Modbus protocol, however, is **packet**
⁴¹⁰ **sniffing** (Figure 2.8): since, as mentioned earlier, network traffic is un-
⁴¹¹ encrypted and the data transmitted is in cleartext, it is sufficient to use
⁴¹² a packet sniffer to capture the network traffic, read the packets and thus

- 413 gather informations about the system such as ip addresses, function codes
 414 of requests and to modify the operation of the devices.

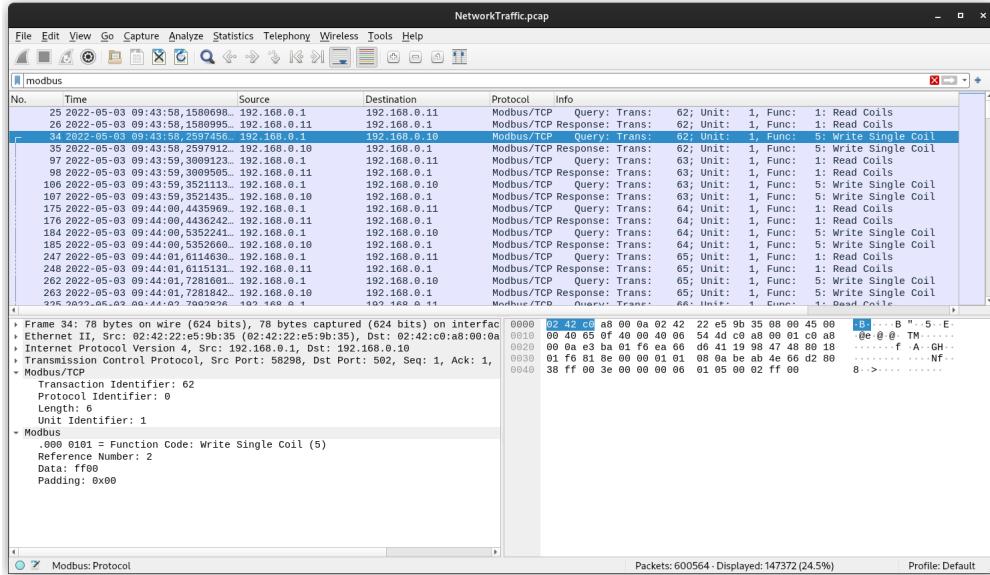

Figure 2.8: Example of packet sniffing on the Modbus protocol

415 To make the Modbus protocol more secure, an encapsulated version
 416 was developed within the *Transport Security Layer* (TLS) cryptographic
 417 protocol, also using mutual authentication. This version of the Modbus
 418 protocol is called **Secure Modbus** or **Modbus TLS**. In addition to this,
 419 Secure Modbus also includes X.509-type certificates to define permissions
 420 and authorisations [17].

421 2.2.6.2 EtherNet/IP

422 *EtherNet/IP* (where IP stands for *Industrial Protocol*) is an open industrial
 423 protocol that allows the *Common Industrial Protocol* (CIP) to run on a
 424 typical Ethernet network [18]. It is supported by ODVA [19].

425 EtherNet/IP uses the major Ethernet standards, such as IEEE 802.3 and
 426 the TCP/IP suite, and implements the CIP protocol stack at the upper layers
 427 of the OSI stack (see Figure 2.9). It is furthermore compatible with the
 428 main Internet standard protocols, such as SNMP, HTTP, FTP and DHCP,

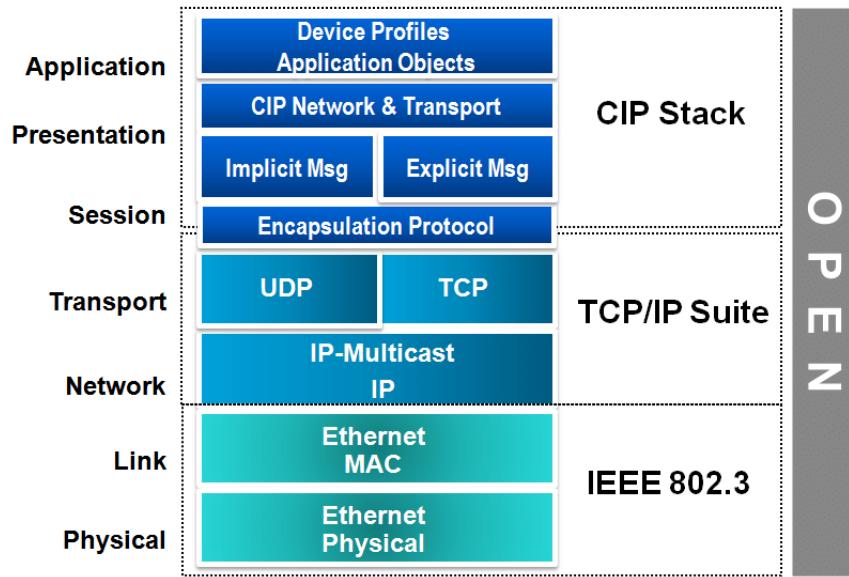

Figure 2.9: OSI model for EtherNet/IP stack

⁴²⁹ and other industrial protocols for data access and exchange such as *Open*
⁴³⁰ *Platform Communication* (OPC).

⁴³¹ **Physical and Data Link layer** The use of the IEEE 802.3 standard allows
⁴³² EtherNet/IP to flexibly adopt different network topologies (star, linear,
⁴³³ ring, etc.) over different connections (copper, fibre optic, wireless, etc.), as
⁴³⁴ well as the possibility to choose the speed of network devices.
⁴³⁵ IEEE 802.3 in addition defines at Data Link layer the *Carrier Sense Multiple*
⁴³⁶ *Access - Collision Detection* (CSMA/CD) protocol, which controls access to
⁴³⁷ the communication channel and prevents collisions.

⁴³⁸ **Transport layer** At the transport level, EtherNet/IP encapsulates mes-
⁴³⁹ sages from the CIP stack into an Ethernet message, so that messages can
⁴⁴⁰ be transmitted from one node to another on the network using the TCP/IP
⁴⁴¹ protocol. EtherNet/IP uses two forms of messaging, as defined by CIP
⁴⁴² standard [18][20]:

- ⁴⁴³ • **unconnected messaging:** used during the connection establishment
⁴⁴⁴ phase and for infrequent, low priority, explicit messages. Uncon-

445 nected messaging uses TCP/IP to transmit messages across the net-
446 work asking for connection resource each time from the *Unconnected*
447 *Message Manager* (UCMM).

- 448 • **connected messaging:** used for frequent message transactions or for
449 real-time I/O data transfers. Connection resources are reserved and
450 configured using communications services available via the UCMM.

451 EtherNet/IP has two types of message connection [18]:

- 452 – **explicit messaging:** *point-to-point* connections to facilitate *request-*
453 *response* transactions between two nodes. These connections use
454 TCP/IP service on port 44818 to transmit messages over Ether-
455 net.
- 456 – **implicit messaging:** this kind of connection moves application-
457 specific **real-time I/O data** at regular intervals. It uses multicast
458 *producer-consumer* model in contrast to the traditional *source-*
459 *destination* model and UDP/IP service (which has lower proto-
460 col overhead and smaller packet size than TCP/IP) on port 2222
461 to transfer data over Ethernet.

462 **Session, Presentation and Application layer** At the upper layers, Ether-
463 Net/IP implements the CIP protocol stack. We will discuss this protocol
464 more in detail in Section 2.2.6.3.

465 2.2.6.3 Common Industrial Protocol (CIP)

466 The *Common Industrial Protocol* (CIP) is an open industrial automation
467 protocol supported by ODVA. It is a **media independent** (or *transport in-*
468 *dependent*) protocol using a *producer-consumer* communication model and
469 providing a **unified architecture** throughout the manufacturing enterprise
470 [21][22].

471 CIP has been adapted in different types of network:

- 472 • **EtherNet/IP**, adaptation to *Transmission Control Protocol* (TCP) tech-
473 nologies
- 474 • **ControlNet**, adaptation to *Concurrent Time Domain Multiple Access*
475 (CTDMA) technologies
- 476 • **DeviceNet**, adaptation to *Controller Area Network* (CAN) technolo-
477 gies
- 478 • **CompoNet**, adaptation to *Time Division Multiple Access* (TDMA) tech-
479 nologies

480 **CIP objects** CIP is a *strictly object oriented* protocol at the upper layers:
481 each object of CIP has **attributes** (data), **services** (commands), **connec-
482 tions**, and **behaviors** (relationship between values and services of attributes)
483 which are defined in the **CIP object library**. The object library supports
484 many common automation devices and functions, such as analog and dig-
485 ital I/O, valves, motion systems, sensors, and actuators. So if the same
486 object is implemented in two or more devices, it will behave the same way
487 in each device [23].

488 **Security** [24] In EtherNet/IP implementation, security issues are the same
489 as in traditional Ethernet, such as network traffic sniffing and spoofing.
490 The use of the UDP protocol also exposes CIP to transmission route ma-
491 nipulation attacks using the *Internet Group Management Protocol* (IGMP)
492 and malicious traffic injection.

493 Regardless of the implementation used, it is recommended that certain
494 basic measures be implemented on the CIP network to ensure a high level
495 of security, such as *integrity, authentication and authorization*.

State of the Art

⁴⁹⁶ **I**N COVENTIONAL IT SYSTEMS, the objective of an attacker is to comprehend the behavior of a program using diverse techniques in order to launch attacks that alter its execution flow, functionalities, or bypass limitations imposed by software licensing. These attack techniques involve an initial examination of the program, consisting of *static analysis* (i.e., analyzing the software without running it) and *dynamic analysis* (i.e., analyzing the program while it is running).

⁵⁰³ The outcome of these two investigative techniques is the *reverse engineering* of the software, which serves the purpose of identifying vulnerabilities or bugs and subsequently strategizing an attack.

⁵⁰⁶ In the context of OT systems, the notion of *reverse engineering* is not limited to its conventional definition, but also includes the concept of **process comprehension**. This term, introduced by Green et al. [25], refers to gaining a comprehensive understanding of the underlying physical process.

⁵¹⁰ There is limited literature available concerning the gathering and analysis of information related to the comprehension and operation of an Industrial Control System (ICS). In Section 3.1, we will provide a brief overview of the existing literature on this topic, and in the subsequent sections, we ⁵¹⁴ will specifically focus on one of the presented papers.

515 3.1 Literature on Process Comprehension

516 **Keliris and Maniatikos** The first approach presented in this section is by
517 Keliris and Maniatikos [26]: they present a methodology for au-
518 tomating the reverse engineering of ICS binaries based on a *modular*
519 *framework* (called ICSREF) that can reverse binaries compiled with
520 CODESYS [27], one of the most popular and widely used PLC com-
521 pilers, irrespective of the language used.

522 **Yuan et al.** Yuan et al. [28] propose a *data-driven* approach to discover-
523 ing cyber-physical systems process behavior from data directly: to
524 achieve this goal, they have implemented a framework whose pur-
525 pose is to identify physical systems and transition logic inference,
526 and to seek to understand the mechanisms underlying these pro-
527 cesses, making furthermore predictions concerning their state trajec-
528 tories based on the discovered models.

529 **Feng et al.** Feng et al. [29] developed a framework that can generate sys-
530 tem *invariant rules* based on machine learning and data mining tech-
531 niques from ICS operational data log. These invariants are then se-
532 lected by systems engineers to derive IDS systems from them.

533 The experiment results on two different testbeds, the *Water Distri-*
534 *bution system* (WaDi) and the *Secure Water Treatment system* (SWaT),
535 both located at the iTrust - Center for Research in Cyber Security at
536 the University of Singapore of Technology and Design [30], show
537 that under the same false positive rate invariant-based IDSs have a
538 higher efficiency in detecting anomalies than IDS systems based on
539 a residual error-based model.

540 **Pal et al.** Pal et al. [31] work is somewhat related to Feng et al.'s: this
541 paper describes a data-driven approach to identifying invariants au-
542 tomatically using *association rules mining* [32] with the aim of generat-
543 ing invariants sometimes hidden from the design layout. The study
544 has the same objective of Feng et al.'s and uses too the iTrust SwaT
545 System as testbed.

546 Currently this technique is limited to only pair wise sensors and
547 actuators: for more accurate invariants generation, the technique
548 adopted must be capable of deriving valid constraints across multiple
549 sensors and actuators.

550 **Winnicki et al.** Winnicki et al. [33] instead propose a different approach
551 to process comprehension based on the *attacker's perspective* and not
552 limited to mere *Denial of Service* (DoS): their approach is to discover
553 the dynamic behavior of the system, in a semi-automated and process-
554 aware way, through *probing*, that is, slightly perturbing the cyber
555 physical system and observing how it reacts to changes and how
556 it returns to its original state. The difficulty and challenge for the
557 attacker is to perturb the system in such a way as to achieve an ob-
558 servable change, but at the same time avoid this change being seen
559 as a system anomaly by the IDSs.

560 **Green et al.** Green et al. [25] also adopt an approach based on the at-
561 tacker's perspective: this approach consists of two practical exam-
562 ples in a *Man in the Middle* (MitM) scenario to obtain, correlate, and
563 understand all the types of information an attacker might need to
564 plan an attack to alter the process while avoiding detection.

565 The paper shows *step-by-step* how to perform a **ICS reconnaissance**, a
566 phase specifically designed to gather extensive intelligence on mul-
567 tiple fronts, including human factors, network and protocol infor-
568 mation, details about the manufacturing process, industrial applica-
569 tions, and potential vulnerabilities. The primary goal is to accumu-
570 late a wealth of information to enhance understanding and aware-
571 ness in these areas [34]).

572 Reconnaissance phase is fundamental to process comprehension and
573 thus to the execution of MitM attacks.

574 **Ceccato et al.** Ceccato et al. [9] propose a methodology based on a *black*
575 *box dynamic analysis* of an ICS using a reverse engineering tool to
576 derive from the scans performed on the memory registers of the ex-

28 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

577 posed PLCs and the Modbus protocol network scans an approximate
578 model of the physical process. This model is obtained by inferring
579 statistical properties, business process and system invariants from
580 data logs.

581 The proposed methodology was tested on a non-trivial case study,
582 using a virtualized testbed inspired by an industrial water treatment
583 plant.

584 In the next section we will examine this latest work in more detail,
585 which will be the basis for my work and thus the subsequent chap-
586 ters of this thesis.

587 3.2 Ceccato et al.'s black-box dynamic analysis 588 for water-tank systems

589 As previously mentioned, the paper introduces a methodology that re-
590 lies on black box dynamic analysis of an Industrial Control System (ICS)
591 and more particularly of its OT network. This methodology involves iden-
592 tifying potential Programmable Logic Controllers (PLCs) within the net-
593 work and scanning the memory registers of these identified controllers.
594 The purpose of this process is to obtain an approximate model of the con-
595 trolled physical process.

596 The primary goal of this black box analysis is to establish a correlation
597 between the different memory registers of the targeted PLCs and funda-
598 mental concepts of an OT network such as sensor values (i.e., measure-
599 ments), actuator commands, setpoints (i.e., range of values of a physical
600 variable), network communications, among others.

601 To accomplish this, the various types of memory registers are analyzed,
602 and attempts are made to determine the nature of the data they might
603 contain.

604 The second goal is to establish a relationship between the dynamic evolu-
605 tion of these fundamental concepts.

606 To accomplish this, Ceccato et al. have developed a prototype tool [35]
607 that facilitates the reverse engineering of the physical system. This tool
608 goes through four distinct phases:

- 609 1. **scanning of the system and data pre-processing:** this phase involves
610 gathering data to generate data logs for the registers of PLCs and for
611 Modbus network communications.
- 612 2. **graphs and statistical analysis:** The collected data is utilized to pro-
613 vide insights into the memory registers associated with the Modbus
614 protocol by leveraging graphs and statistical data. This analysis ap-
615 proach offers valuable information about the characteristics and pat-
616 terns of the memory registers.
- 617 3. **invariants inference and analysis:** generates system invariants, which
618 are used to identify specific patterns and regularities within the sys-
619 tem. Additionally, this phase provides users with the capability to
620 view invariants related to a particular sensor or actuator.
- 621 4. **business process mining and analysis:** Using event logs, this phase
622 involves reconstructing the business process that depicts how a pro-
623 cess is executed. This step enables a thorough understanding of the
624 sequence of events that occur in the system and how they are in-
625 terrelated, ultimately leading to a comprehensive overview of the
626 business process.

627 Figure 3.1 presents a schematic representation of the stages and the
628 workflow associated with this work, specifying tools and technologies
629 used. In the subsequent sections of this chapter, we will provide a detailed
630 exploration of each of these phases, offering a comprehensive understand-
631 ing of the entire process.

632 3.2.1 Testbed

633 Before delving into the description of the methodology's different phases,
634 let's first examine the testbed utilized to evaluate this approach. The testbed

30 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

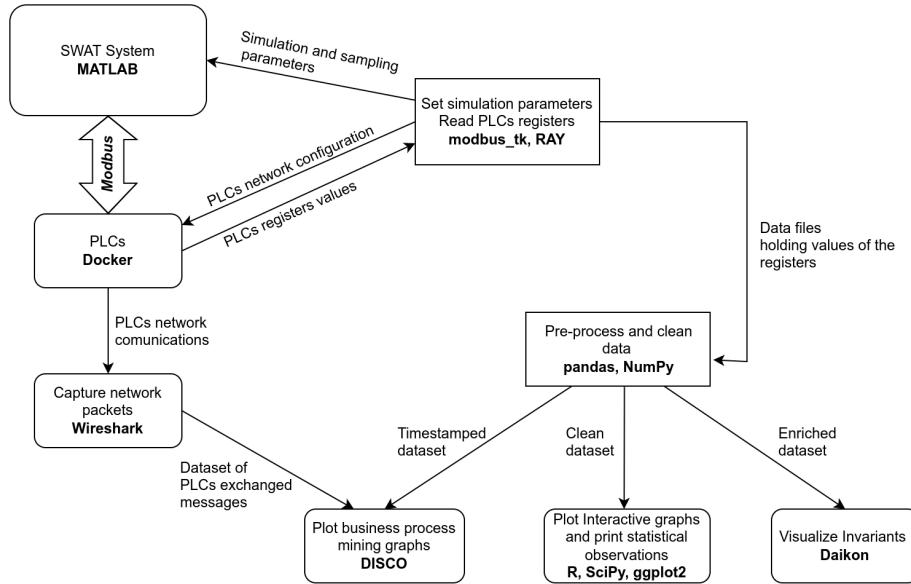

Figure 3.1: Workflow of Ceccato et al.'s stages and operations with used tools

635 employed for testing purposes is a (very) simplified rendition of the iTrust
 636 SWaT system [36], as implemented by Lanotte et al. [37]. Figure 3.2 pro-
 637 vides a graphical representation of the testbed. This simplified version
 638 comprises three stages, each governed by a dedicated PLC.

639 **Stage 1** During the initial stage, a **tank** referred to as T-201 with a capacity
 640 of 80 gallons is filled with raw water using the P-101 pump. Con-
 641 nected to the T-201 tank, the MV-301 motorized valve flushes out the
 642 accumulated water from the tank, directing it to the next stage. Ini-
 643 tially, the water flows from the T-201 tank to the *filtration unit* (which
 644 is not specifically identified by any sensor), and subsequently to a
 645 **second tank** denoted as T-202, with a capacity of 20 gallons.

646 **Stage 2** At the second stage, the water stored in tank T-202 flows into the
 647 *reverse osmosis unit* (RO), which serves as both a valve and a continu-
 648 ous water extractor. The purpose of the RO unit is to reduce organic
 649 impurities present in the water. Subsequently, the water flows from
 650 the *RO unit* to the third and final stage of the system.

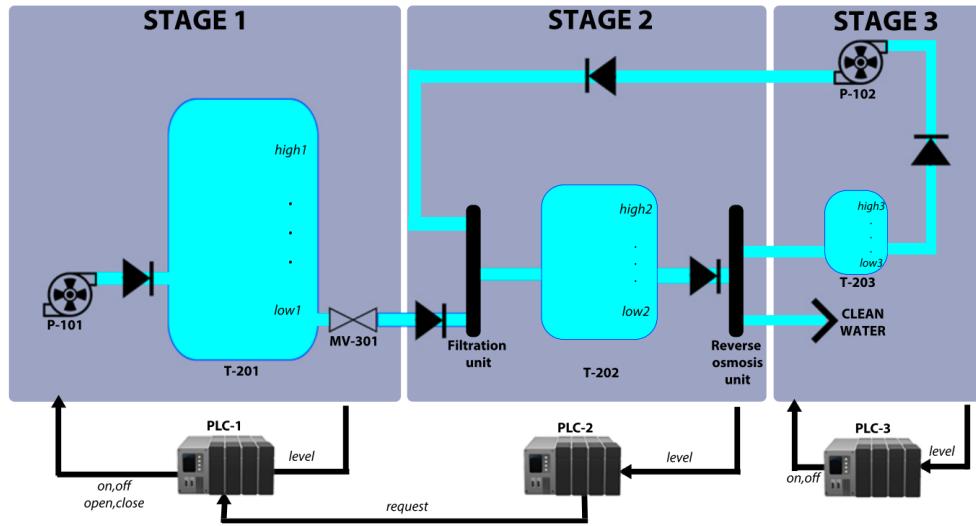

Figure 3.2: The simplified SWaT system used for running Ceccato et al. methodology

651 **Stage 3** At the third stage, the water coming from the *RO unit* undergoes
 652 division based on whether it meets the required standards. If the
 653 water is deemed clean and meets the standards, it is directed into
 654 the distribution system. However, if the water fails to meet the stan-
 655 dards, it is redirected to a *backwash tank* identified as T-203, which
 656 has a capacity of one gallon. The water stored in this tank is then
 657 pumped back to the stage 2 *filtration unit* using pump P-102.

658 As previously mentioned, each stage of the system is handled via a
 659 dedicated PLC, namely PLC1, PLC2, and PLC3, which are responsible for
 660 controlling their respective stages. Let's briefly explore the behavior of
 661 each PLC:

662 **PLC1** PLC1 monitors the level of tank T-201 and distinguishes three dif-
 663 ferent cases based on the level readings:

- 664 1. when the level of tank T-201 reaches the defined *low setpoint*
 665 *low1* (which is hardcoded in a specific memory register), PLC1
 666 **opens pump P-101** and **closes valve MV-301**. This configura-
 667 tion allows the tank to be filled with water;

32 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

- 668 2. if the level of T-201 reaches the *high setpoint high1* (which is also
669 hardcoded in a specific memory register), then the pump **P-101**
670 **is closed**;
671 3. in cases where the level of T-201 is between the *low setpoint low1*
672 and the *high setpoint high1*, PLC1 waits for a request from PLC2
673 to open or close the valve MV-301. If a request to open the valve
674 MV-301 is received, water will flow from T-201 to T-202. How-
675 ever, if no request is received, the valve remains closed. In both
676 situations, the pump P-101 remains closed.

677 **PLC2** PLC2 monitors the level of tank T-202 and adjusts its behavior based
678 on the water level. There are three cases to consider:

- 679 1. when the water level in tank T-202 reaches *low setpoint low2* (also
680 hardcoded in the memory registers), PLC2 sends a request to
681 PLC1 through a Modbus channel to **open valve MV-301**. This
682 request is made in order to allow the water to flow from tank T-
683 201 to tank T-202. The transmission channel between the PLCs
684 is established by copying a boolean value from a memory reg-
685 ister of PLC2 to a corresponding register of PLC1.
686 2. when the water level in tank T-202 reaches the *high setpoint high2*
687 value (also hardcoded in the memory registers), PLC2 sends a
688 **close request to PLC1 for valve MV-301**. This request prompts
689 PLC1 to close the valve, stopping the flow of water from tank
690 T-201 to tank T-202.
691 3. In cases where the water level in tank T-202 is between the low
692 and high setpoints, the valve MV-301 remains in its current state
693 (open or closed) while the tank is either filling or emptying.

694 **PLC3** PLC3 monitors the level of the T-203 backwash tank and adjusts its
695 behavior accordingly. There are two cases to consider:

- 696 1. If the water level in the backwash tank reaches the *low setpoint*

697 *low3, PLC3 sets pump P103 to off.* This allows the backwash
698 tank to be filled.

- 699 2. If the water level in the backwash tank reaches the *high setpoint*
700 *high3, PLC3 opens pump P103.* This action triggers the pump-
701 ing of the entire content of the backwash tank back to the filter
702 unit of T-202.

703 3.2.2 Scanning of the System and Data Pre-processing

704 **Scanning tool** The Ceccato et al. scanning tool extends and generalizes
705 a project I did [38] for the "Network Security" and "Cyber Security for IoT"
706 courses taught by Professors Massimo Merro and Mariano Ceccato, re-
707 spectively, in the 2020/21 academic year. The original project involved,
708 in its first part, the recognition within a network of potential PLCs lis-
709 tening on the standard Modbus TCP port 502 using the Nmap module
710 for Python, obtaining the corresponding IP addresses: then a (sequential)
711 scan of a given range of the memory registers of the found PLCs was per-
712 formed to collect the register data. The data thus collected were saved to
713 a file in *JavaScript Object Notation* (JSON) format for later use in the second
714 part of my project.

715 The scanning tool by Ceccato et. al works in a similar way, but extends
716 what originally did by trying to discover other ports on which the Mod-
717 bus protocol might be listening (since in many realities Modbus runs on
718 different ports than the standard one, according to the concept of *security*
719 *by obscurity*) and, most importantly, by **parallelizing and distributing the**
720 **scan** of PLC memory registers through the Ray module [39], specifying
721 moreover the desired granularity of the capture. An example of raw data
722 capture can be seen at Listing 3.1:

```
723     "127.0.0.1/8502/2022-05-03 12_10_00.591": {  
724         "DiscreteInputRegisters": {"%IX0.0": "0"},  
725         "InputRegisters": {"%IW0": "53"},  
726         "HoldingOutputRegisters": {"%QW0": "0"},  
727         "MemoryRegisters": {"%MW0": "40", "%MW1": "80"},
```

34 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

```
728     "Coils": {"%QX0.0": "0"}}
```

Listing 3.1: Example of registers capture

729 The captured data includes PLC's IP address, Modbus port and timestamp
730 (first line), type and name of registers with their values read from the scan
731 (subsequent lines).

732 The tool furthermore offers the possibility, in parallel to the memory
733 registers scan, of **sniffing network traffic** related to the Modbus protocol
734 using the *Man in the Middle* (MitM) technique on the supervisory control
735 network using a Python wrapper for tshark/Wireshark [40] [41]. An ex-
736 ample of raw data obtained with this sniffing can be seen in Listing 3.2:

```
737     Time,Source,Destination,Protocol,Length,Function Code,  
738     ↳ Destination Port,Source Port,Data,Frame length on the  
739     ↳ wire,Bit Value,Request Frame,Reference Number,Info

```

Listing 3.2: Example of raw network capture

743 **Data Pre-processing** The data collected by scanning the memory regis-
744 ters of the PLCs are then reprocessed by a Python script and converted
745 in order to create a distinct raw dataset in *Comma Separated Value* for-
746 mat (CSV) for each PLC, containing the memory register values associ-
747 ated with the corresponding controller registers. These datasets are repro-
748 cessed again through the Python modules for **pandas** [42] and **NumPy** [43]
749 by another script to first perform a **data cleanup**, removing all unused reg-
750 isters, **merged** into a single dataset, and finally **enriched** with additional
751 data, such as the **previous value** of all registers and the the **measurement**
752 **slope**, that is, the trend of the water level in the system tanks along the
753 system cycles¹. See 3.2.7 for more detail.

754

¹Not all additional data are calculated and entered automatically by the tool: some are manually inserted.

This process leads to the creation of two copies of the full dataset: one enriched with the additional data, but not timestamped, which will be used for the invariant analysis; the other unenriched, but timestamped, which will be used for business process mining.

3.2.3 Graphs and Statistical Analysis

The paper mentions the presence of a *mild graph analysis*, performed using the framework **R** [44] for statistical analysis at the time of data gathering to find any uncovered patterns, trends and identify measurements and/or actuator commands through the analysis of registers holding mutable values.

There is actually no trace of this within the tool: *graph analysis* and *statistical analysis* of the data contained in the PLC memory registers are instead performed using the **matplotlib libraries** and statistical algorithms made available by the **SciPy libraries** [45], through two separate Python scripts (see Figure 3.3).

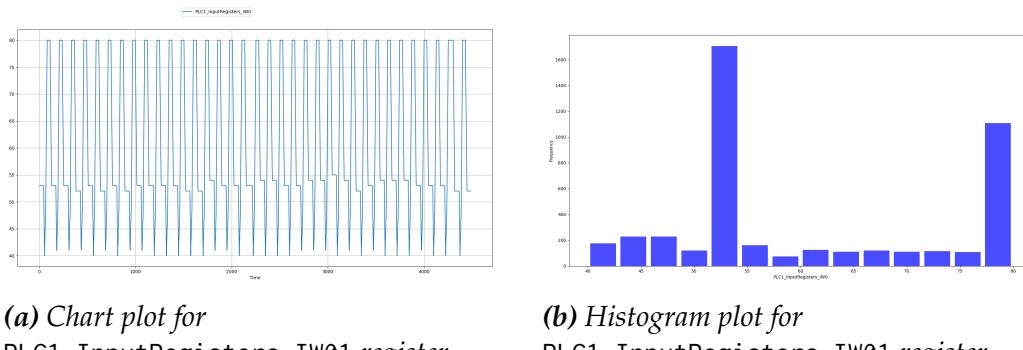

Figure 3.3: Output graphs from graph analysis

The first script plots the charts, one at the time, of certain registers entered by the user from the command line, plots in which one can see the trend of the data and get a first basic idea of what that particular register contains (a measurement, an actuation, a hardcoded setpoint, ...) and possibly the trend; the second script, instead, shows a **histogram and sta-**

36 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

775 **tistical informations** about the register entered as command-line input.

776 These informations include:

- 777 • the mean, median, standard deviation, maximum value and mini-
778 mum value
- 779 • two tests for the statistical distribution: *Chi-squared* test for unifor-
780 mity and *Shapiro-Wilk* test for normality, as shown in Listing 3.3:

```
781     Chi-squared test for uniformity
782     Distance      pvalue      Uniform?
783     12488.340    0.00000000    NO
784
785     Shapiro-Wilk test for normality
786     Test statistic   pvalue      Normal?
787     0.844        0.00000000    NO
788
789     Stats of PLC1_InputRegisters_IW0
790     Sample mean = 60.8881; Stddev = 13.0164; max = 80; min =
791     ↪ 40 for 4488 values
```

Listing 3.3: Statistical data for PLC1_InputRegisters_IW0 register

792 3.2.4 Invariant Inference and Analysis

793 For invariant analysis Ceccato et al. rely on **Daikon** [46], a framework
794 to **dynamically detect likely invariants** within a program. An *invariant*
795 is a property that holds at one or more points in a program, properties
796 that are not normally made explicit in the code, but within assert state-
797 ments, documentation and formal specifications: invariants are useful in
798 understanding the behavior of a program (in our case, of the cyber physi-
799 cal system).

800 Daikon uses *machine learning* techniques applied to arbitrary data with
801 the possibility of setting custom conditions for analysis by using a spe-
802 cific file [47] with a *.spinfo* extension (see Listing 3.4). The framework is
803 designed to find the invariants of a program, with various supported pro-
804 gramming languages, starting from the direct execution of the program

805 itself or passing as input the execution run (typically a file in CSV format);
 806 the authors of the paper tried to apply it by analogy also to the execution
 807 runs of a cyber physical system, to extract the invariants of this system.

```
808 PPT_NAME aprogram.point:::POINT
809 VAR1 > VAR2
810 VAR1 == VAR3 && VAR1 != VAR4
```

Listing 3.4: Generic example of a .spininfo file for customizing rules in Daikon

811 Therefore, Daikon is fed with the enriched dataset obtained in the pre-
 812 processing phase²: a simple bash script launches Daikon (optionally spec-
 813 ifying the desired condition for analysis in the *.spininfo* file), which output is
 814 simply redirected to a text file containing the general invariants of the sys-
 815 tem (i.e., valid regardless of any custom condition specified), those gener-
 816 ated based on the custom condition in the *.spininfo* file, and those generated
 817 based on the negation of the condition (see Listing 3.5 below).

```
818 =====
819 aprogram.point:::POINT
820 PLC2_MemoryRegisters_MW1 == PLC3_MemoryRegisters_MW1
821 PLC1_MemoryRegisters_MW0 == 40.0
822 PLC1_MemoryRegisters_MW1 == 80.0
823 PLC1_Coils_QX00 one of { 0.0, 1.0 }
824 [...]
825 =====
826 aprogram.point:::POINT; condition="PLC1_InputRegisters_IW0
827   ↪ > 60"
828 PLC1_InputRegisters_IW0 > PLC1_MemoryRegisters_MW0
829 PLC1_InputRegisters_IW0 > PLC1_Min_safety
830 PLC1_MemoryRegisters_MW0 < prev_PLC1_InputRegisters_IW0
831 [...]
832 =====
833 aprogram.point:::POINT; condition="not(
834   ↪ PLC1_InputRegisters_IW0 > 60)"
835 PLC1_InputRegisters_IW0 < PLC1_MemoryRegisters_MW1
836 PLC1_InputRegisters_IW0 < PLC1_Max_safety
```

²In the paper, timestamped dataset is explicitly mentioned as input: from the tests performed, Daikon seems to ignore timestamps, hence it is indifferent whether the dataset is timestamped or not

38 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

```
837     PLC1_MemoryRegisters_MW1 > prev_PLC1_InputRegisters_IW0  
838     [...]
```

Listing 3.5: The three sections of Daikon analysis outcomes

839 When the analysis is finished, the user is asked to enter the name of a reg-
840 istry to view its related invariants.

841
842 Some examples of invariants derived from the enriched dataset may be:

- 843 • measurements bounded by some setpoint;
844 • actuators state changes occurred in the proximity of setpoints or,
845 vice versa, proximity of setpoints upon the occurrence of an actuator
846 state change;
847 • state invariants of some actuators correspond to a specific trend in
848 the evolution of the measurements (ascending, descending, or sta-
849 ble) or, vice versa, the measurements trend corresponds to a specific
850 state invariant of some actuators.

851 3.2.5 Business Process Mining and Analysis

852 *Process mining* is the analysis of operational processes based on the
853 event log [48]: the aim of this analysis is to **extract useful informations**
854 from the event data to **reconstruct and understand the behavior** of the
855 business process and how it was actually performed.

856
857 In the considered system, process mining begins by analyzing the event
858 logs derived from scanning the memory registers of the PLCs and moni-
859 toring the network communications associated with the Modbus protocol,
860 as detailed in Subsection 3.2.2. These event logs serve as the *execution trace*
861 of the system. A Java program is utilized to extract and consolidate infor-
862 mation from these event logs, resulting in a CSV format file that captures
863 the relevant data.

864 This file is fed to **Disco** [49], a commercial process mining tool, which

generates an *activity diagram* similar to UML Activity Diagram and whose nodes represent the activities while the edges represent the relations between these activities. In Figure 3.4 we can see an example of this diagram referred to PLC2 of the testbed: nodes represent the trend of register associated with measurement, actuator state changes, and communications between PLCs involving these state changes, while edges represent transitions with their associated time duration and frequency.

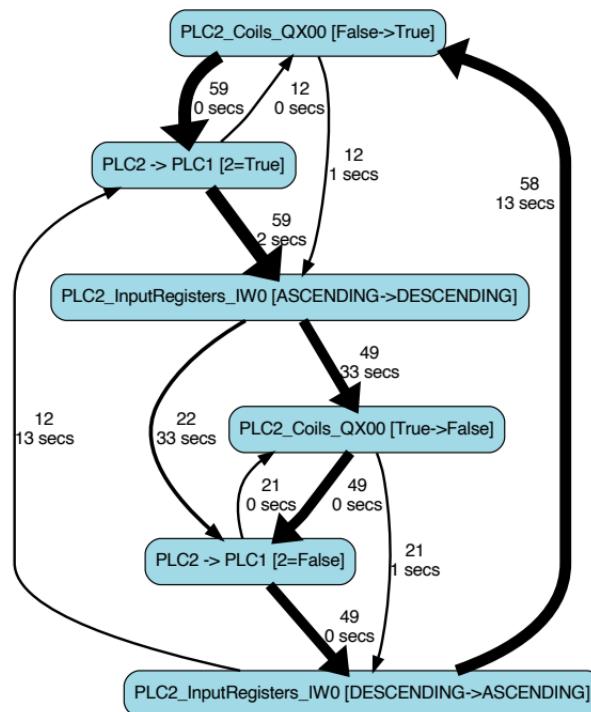

Figure 3.4: An example of Disco generated activity diagram for PLC2

The *business process* obtained in this way provides an **overview of the system** and makes it possible to **make conjectures** about its behavior, particularly between changes in actuator state and measurement trends (i.e., a given change in state of some actuators corresponds to a specific measurement trend and vice versa), and with the possibility of **establishing causality** between Modbus communications and state changes within the physical system.

40 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

879 3.2.6 Application

880 In this section we will see how the black box analysis presented above
881 in its various phases is applied in practice, using the testbed described in
882 Subsection 3.2.1. The methodology supports a *top-down approach*: that
883 is, we start with an overview of the industrial process and then gradually
884 refine our understanding of the process by descending to a higher and
885 higher level of detail based on the results of the previous analyses and
886 focusing on the most interesting parts of the system for further in-depth
887 analysis.

888 **Data Collection and Pre-processing** According to what is described in
889 the paper, the data gathering process lasted six hours, with a granular-
890 ity of one data point per second (a full system cycle takes approximately
891 30 minutes). Each datapoint consists of 168 attributes (55 registers plus
892 a special register concerning the tank slope of each PLC) after the en-
893 richment. In addition, IP addresses are automatically replaced by an ab-
894 stract name identified by the prefix PLC followed by a progressive integer
895 (PLC1, PLC2, PLC3), in order to make reading easier.

896 **Graphs and Statistical Analysis** Graphs and Statistical Analysis revealed
897 three properties regarding the contents of the registers:

898 **Property 1:** PLC1_MemoryRegisters_MW0, PLC1_MemoryRegisters_MW1,
899 PLC2_MemoryRegisters_MW0, PLC2_MemoryRegisters_MW1,
900 PLC3_MemoryRegisters_MW0 and PLC3_MemoryRegisters_MW1
901 registers contain constant integer values (40, 80, 10, 20, 0, 10 respec-
902 tively)³. The authors speculate that they may be (relative) hardcoded
903 **setpoints**.

³From my tests on the original tool and dataset, the PLC3_MemoryRegisters_MW0 register is deleted during the *pre-processing* phase, as it is recognized as an unused register because of the constant value "0" it takes on. This leads me to assume that the properties are derived from a human read of the dataset prior to the *pre-processing* phase.

904 **Property 2:** PLC1_Coils_QX01, PLC1_Coils_QX02, PLC2_Coils_QX01,
 905 PLC2_Coils_QX02, PLC3_Coils_QX01 and PLC3_Coils_QX03 contain mu-
 906 table binary (Boolean) values. The authors speculate that these reg-
 907 isters can be associated with the **actuators** of the system.

908 **Property 3:** PLC1_InputRegisters_IW0, PLC2_InputRegisters_IW0 and
 909 PLC3_InputRegisters_IW0 registers contain mutable values.

910 Property 3 suggests that those registers might contain **values related to**
 911 **measurements**: it is therefore necessary to investigate further to see if the
 912 conjecture (referred to as *Conjecture 1* in the paper) is correct.

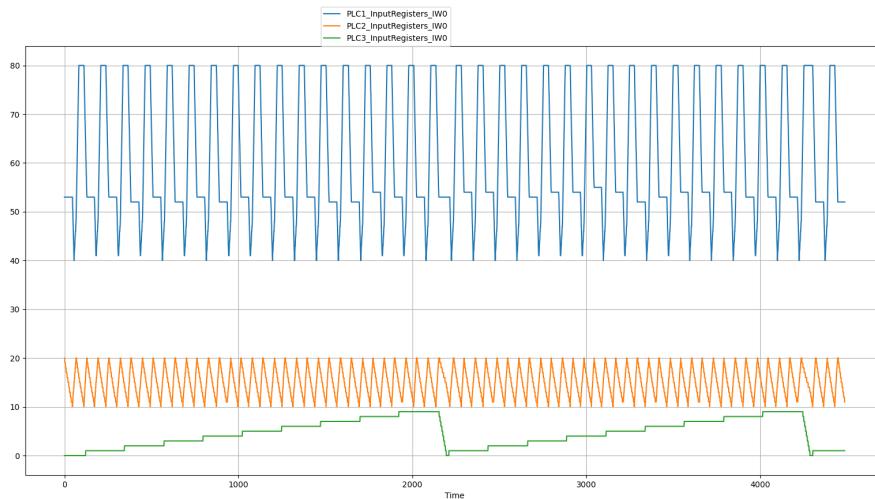

Figure 3.5: Execution traces of InputRegisters_IW0 on the three PLCs

913 The graph analysis of the InputRegisters_IW0 registers of the three
 914 PLCs (summarized in Figure 3.5 with a single plot) not only seems to con-
 915 firm the conjecture, but also allows the measurements to be correlated with
 916 the contents of the MemoryRegisters_MW0 and MemoryRegisters_MW1 regis-
 917 ters to the measurements, which may well represent the **relative setpoints**
 918 **of the measurements**. Hence, we have *Conjecture 2* described in the paper
 919 referring to the relative setpoints:

920

921 **Conjecture 2:**

922 - the relative setpoints for PLC1_InputRegisters_IW0 are 40 and 80;

42 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

- 923 - the relative setpoints for PLC2_InputRegisters_IW0 are 10 and 20;
924 - the relative setpoints for PLC3_InputRegisters_IW0 0 and 9.

925 Further confirmation of this conjecture may come from statistical anal-
926 ysis. Indeed, in the example in Listing 3.1, some statistical data are given
927 for the register PLC1_InputRegisters_IW0, including the maximum value
928 and the minimum value: these values are, in fact, 80 and 40 respectively.

929 **Business Process Mining and Analysis** With Business Process Mining,
930 the authors aim to **visualize and highlight relevant system behaviors** by
931 relating PLC states and Modbus commands.

932 Through analysis of the activity diagrams shown in Figure 3.6, drawn
933 through Disco, they derive the following properties and conjectures:

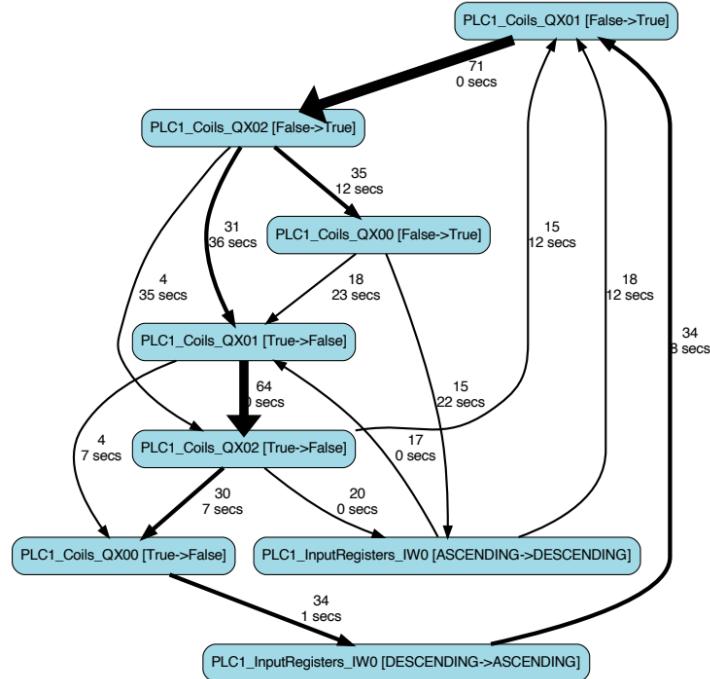

934 **Property 4:** PLC2 sends messages to PLC1 (see Figure 3.6b) which are
935 recorded to PLC1_Coils_QX02.

936 **Conjecture 3:** PLC2_Coils_QX00 determines the trend in tank T-202 (Figure
937 3.6b).

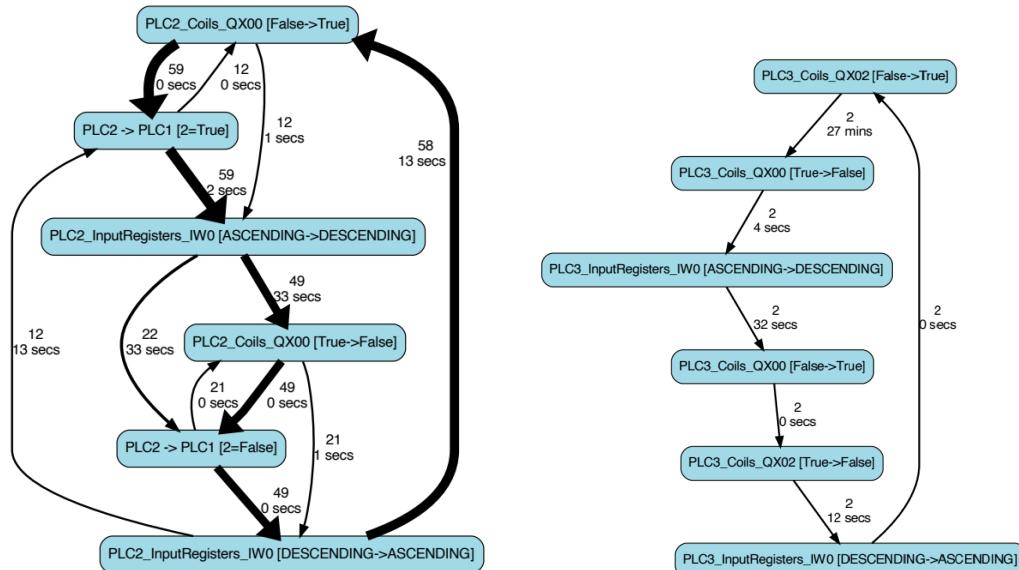

938 When this register is set to *True*, the input register PLC2_InputRegisters_IW0
939 related to the tank controlled by PLC2 starts an **ascending trend**; vice
940 versa, when the coil register is set to *False*, the input register starts a
941 **descending trend**.

942 **Conjecture 4:** If PLC1_Coils_QX00 change his value to True, trend in tank
943 T-201, related to PLC1_InputRegisters_IW0 and controlled by PLC1,
944 become **ascending** (see Figure 3.6a)

945 **Conjecture 5:** PLC3_Coils_QX00 starts a **decreasing trend** in tank T-203, re-
946 lated to PLC3_InputRegisters_IW0 and controlled by PLC3, whereas
947 PLC3_Coils_QX02 starts an **increasing trend** on the tank (see Figure
948 3.6c)

(a) States in PLC1

(b) States and Modbus command in PLC2

(c) States in PLC3

Figure 3.6: Business process with states and Modbus commands for the three PLCs

44 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

949 **Invariant Inference and Analysis** The last phase of the analysis of the
950 example industrial system is invariant analysis, performed through Daikon
951 framework. At this stage, an attempt will be made to confirm what has
952 been seen previously and to derive new properties of the system based on
953 the results of the Daikon analysis.

954 To get gradually more and more accurate results, the authors presum-
955 ably performed more than one analysis with Daikon, including certain
956 rules within the *splitter information file* (see Section 3.2.4 and Listing 3.4)
957 based on specific conditions placed on the measurements, for example, the
958 level of water contained in a tank. Given moreover the massive amount
959 of invariants generated by Daikon's output, it is not easy to identify and
960 correlate those that are actually useful for analysis: this must be done man-
961 ually.

962 However, it was possible to have confirmation of the conjectures made
963 in the previous stages of the analysis: starting with the setpoints, analyz-
964 ing the output of the invariants returned by Daikon⁴ reveals that

965
966 PLC1_InputRegisters_IW0 >= PLC1_MemoryRegisters_MW0 == 40.0
967 PLC1_InputRegisters_IW0 <= PLC1_MemoryRegisters_MW1 == 80.0
968 PLC2_InputRegisters_IW0 >= PLC2_MemoryRegisters_MW0 == 10.0
969 PLC2_InputRegisters_IW0 <= PLC2_MemoryRegisters_MW1 == 20.0
970 PLC3_InputRegisters_IW0 >= PLC3_MemoryRegisters_MW0 == 0.0
971 PLC3_InputRegisters_IW0 <= PLC3_MemoryRegisters_MW1 == 9.0
972
973 i.e., that the MemoryRegisters_MW0 and MemoryRegisters_MW1 registers of
974 each PLC contain the **absolute minimum and maximum setpoints**, re-
975 spectively (*Property 5*).

976 There is also a confirmation regarding *Property 4*: from the computed
977 invariants it can be seen that

⁴The invariants shown here are a manual summary and derivation of those actually returned in output by Daikon. We will discuss this more in Section 3.2.7

978

979 PLC1_Coils_QX01 == PLC1_Coils_QX02 == PLC2_Coils_QX00

980

981 and from this derive that there is a **communication channel between PLC2**
982 **and PLC1**, where the value of PLC2_Coils_QX00 is copied to PLC1_Coils_QX01
983 and PLC1_Coils_QX02 (*Property 6*).

984 Regarding the **relationships between actuator state changes and mea-**
985 **surement trends**, invariant analysis yields the results summarized in the
986 following rules:

987 **Property 7:** Tank T-202 level *increases* iff PLC1_Coils_QX01 == True. Oth-
988 erwise, if PLC1_Coils_QX01 == False will be *non-increasing*.

989 This is because if the coil is *True* the condition

990 PLC2_InputRegisters_IW0 == PLC2_MemoryRegisters_MW0 == 20.0 && PLC2_slope > 0

991 is verified. On the opposite hand, if the coil is *False*, the condition992 PLC2_InputRegisters_IW0 == PLC2_MemoryRegisters_MW0 == 20.0 && PLC2_slope <= 0 is verified. The
993 *slope* is increasing if > 0, decreasing if < 0, stable otherwise.

994 **Property 8:** Tank T-201 level *increases* iff PLC1_Coils_QX00 == True. On the
995 other hand, if PLC1_Coils_QX00 == False and if PLC1_Coils_QX01 ==
996 *True* the level will be *non-decreasing*.

997 **Property 9:** Tank T-203 level *decreases* iff PLC3_Coils_QX00 == True. It will
998 be *non-decreasing* if PLC1_Coils_QX00 == False.

999 The last two properties concern the **relationship between actuator state**
1000 **changes and the setpoints**: it is intended to check what happens to the
1001 actuators when the water level reaches one of these setpoints. From the
1002 analysis of the relevant invariants, the following properties are derived:

1003 **Property 10:** Tank T-201 reaches the upper absolute setpoint when
1004 PLC1_Coils_QX00 changes its state from *True* to *False*. If the coil changes
1005 from *False* to *True*, the tank reaches its absolute lower setpoint.

46 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

1006 **Property 11:** Tank T-203 reaches the upper absolute setpoint when
1007 PLC3_Coils_QX00 changes its state from *True* to *False*. If the coil changes
1008 from *False* to *True*, the tank reaches its absolute lower setpoint.

1009 3.2.7 Limitations

1010 The methodology proposed by Ceccato et al. is certainly valid and
1011 offers a good starting point for approaching the reverse engineering of
1012 an industrial control system from the attacker's perspective, while also
1013 providing a tool to perform this task.

1014 The limitations of this approach, however, all lie in the tool mentioned
1015 above and also in the testbed described in Section 3.2.1. In this section
1016 we will explain which are the criticisms of each phase, while in Chapter 4
1017 we will formulate proposals to improve and make this methodology more
1018 efficient.

1019 **General Criticism** There are several critical aspects associated with the
1020 application of this approach: the primary one concerns the fact that the
1021 proposed tool seems to be built specifically for the testbed used and that
1022 it is not applicable to other contexts, even to the same type of industrial
1023 control system (water treatment systems, in this case).

1024 What severely limits the analysis performed with the tool implemented
1025 by Ceccato et al. is the use of *ad hoc* solutions and *a posteriori* interventions
1026 done manually on the datasets after the data gathering process: we will
1027 discuss this last aspect in more detail later.

1028 Moreover, there is the presence of many *hardcoded* variables and condi-
1029 tions within the scripts: this makes the system unconfigurable and unable
1030 to properly perform the various stages of the analysis as errors can occur
1031 due to incorrect data and mismatches with the system under analysis.

1032 Having considered, furthermore, only the Modbus protocol for network
1033 communications between the PLCs is another major limiting factor and

1034 does not help the methodology to be adaptable to different systems com-
1035 municating with different protocols (sometimes even multiple ones on the
1036 same system).

1037 Let us now look at the limitations and critical aspects of each phase.

1038 **Testbed** The testbed environment used by Ceccato et. al is entirely simu-
1039 lated, from the physical system to the control system. The PLCs were built
1040 with **OpenPLC** [50] in a Docker environment [51], while the physics part
1041 was built through **Simulink** [52].

1042 OpenPLC is an open source cross-platform software that simulates the
1043 hardware and software functionality of a physical PLC and also offers a
1044 complete editor for PLC program development with support for all stan-
1045 dard languages: *Ladder Logic* (LD), *Function Block Diagram* (FBD), *Instruc-*
1046 *tion List* (IL), *Structured Text* (ST), and *Sequential Function Chart* (SFC).

1047 It is for sure an excellent choice for creating a zero-cost industrial or home
1048 automation and *Internet of Things* (IoT) system that is easy to manage via a
1049 dedicated, comprehensive and functional web interface. In spite of these
1050 undoubted merits, however, there are (at the moment) **very few supported**
1051 **protocols**: the main one and also referred to in the official documentation
1052 is **Modbus**, while the other protocol is DNP3.

1053 **First limitation** The biggest problem with the testbed, however, is not
1054 with the controller part, but with the **physical part**: first of all, it
1055 must be said that although this is something purely demonstrative
1056 even though it is fully functional, the implemented Simulink model
1057 is really **oversimplified** compared to other testbeds. In fact, in the
1058 entire system there are only three actuators, two of which are con-
1059 nected to the same tank and controlled by the same PLC, and sensors
1060 related only to the water level in the system's tanks: in a real sys-
1061 tem there are many more *field devices*, which can monitor and control
1062 other aspects of the system beyond the mere contents of the tanks.
1063 Consider, for example, measuring and controlling the chemicals in

48 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

1064 the water, the pressure of the liquid in the filter unit, or more simply
1065 the amount of water flow at a given point or time.

1066 All these must be considered and represent a number of additional
1067 variables that makes analysis and consequently reverse engineering
1068 of the system more difficult.

1069 ***Second limitation*** The second critical aspect concerns the **simulation of**
1070 **the physics of the liquid** inside the tanks: Simulink does not con-
1071 sider the fact that inside a tank that is filling (emptying) the liquid
1072 in it undergoes **fluctuations** which cause the level sensor not to see
1073 the water level constantly increasing (decreasing) or at most being
1074 stable at each point of detection. Figure 3.7 exemplifies more clearly
1075 with an example the concept just expressed: these oscillations cause
1076 a **perturbation** in the data.

1077 This issue leads to the difficulty, on a real physical system, of **cor-**
1078 **rectly calculating the trend of a measurement** by using the slope
1079 attribute: if this was obtained with a too low granularity, the trend
1080 will be oscillating between increasing and decreasing even when in
1081 reality this would be in general increasing (decreasing) or stable; on
1082 the other hand, if the slope was obtained with a too high granularity
1083 there is a loss of information and the trend may be "flattened" with
1084 respect to reality.

1085 In the present case, the slope in the Simulink model was calculated
1086 statically with a (very) low granularity, 5 and 6 seconds according
1087 to the Properties 7 and 9 described in the original paper: an aver-
1088 agely careful reader will have already guessed that this granularity
1089 is inapplicable to the real system in Figure 3.7b. As we will later see,
1090 we need to **operate on the data perturbations** to be able to obtain a
1091 suitable granularity and a correct calculation of the slope and conse-
1092 quently of the measurement trend.

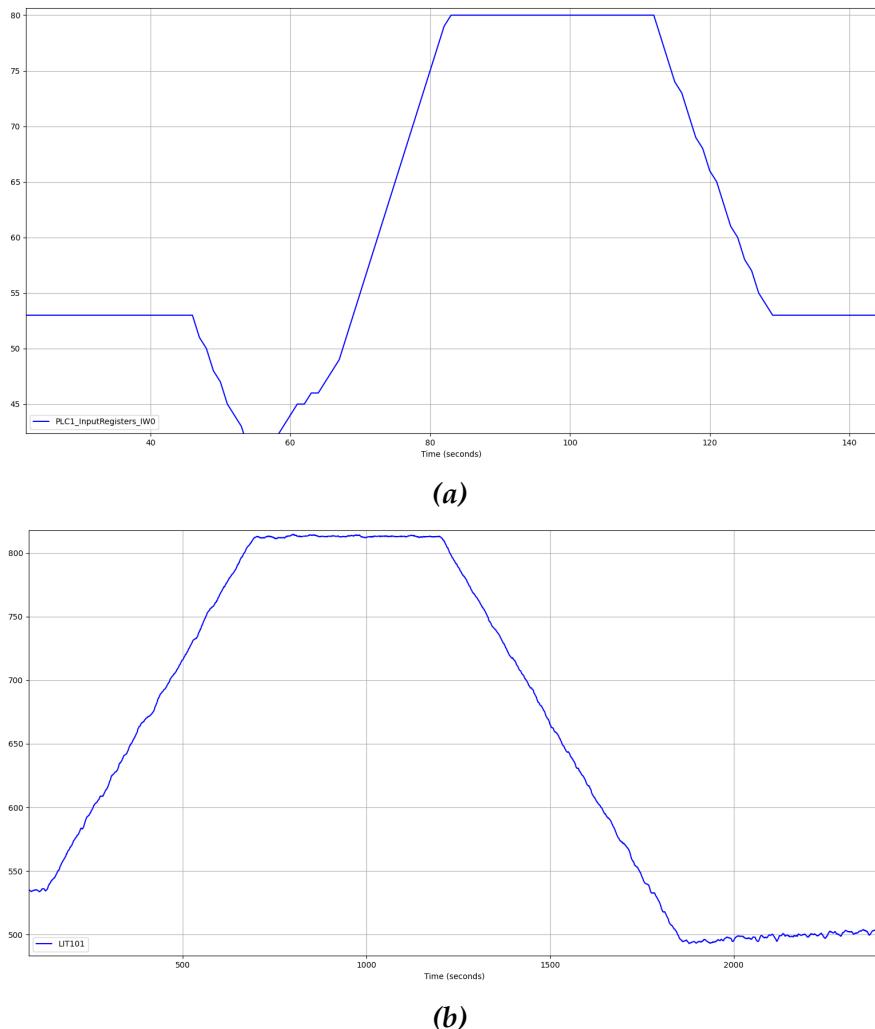

Figure 3.7: Water physics compared: simulated physics in the Simulink model (a) and physics in a real system (iTrust SWaT) (b). Fluctuations in the tank level in (b), almost completely absent in (a), can be appreciated.

1093 **Pre-processing** In the pre-processing phase, the authors make use of a
 1094 Python script to merge all the datasets of the individual PLCs into a single
 1095 dataset, remove the (supposedly) unused registers, and finally enrich the
 1096 obtained dataset with additional attributes. These attributes, as seen in
 1097 3.2.2, are:

- 1098 • the **previous value** of all registers;

50 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

- 1099 • some **additional relative setpoints** named PLC x _Max_safety and
1100 PLC x _Min_safety (where x is the PLC number), which represent a
1101 kind of alert on reaching the maximum and minimum water levels
1102 of the tanks;
- 1103 • the **measurement slope**.

1104 ***First limitation*** Merging the datasets of all individual PLCs into a single
1105 dataset representing the entire system can be a sound practice if the
1106 system to be analyzed is (very) small as is the testbed analyzed here,
1107 consisting of a few PLCs and especially a few registers. If, however,
1108 the complexity of the system increases, this type of merging can be-
1109 come counterproductive and make it difficult to analyze and under-
1110 stand the data obtained in subsequent steps.

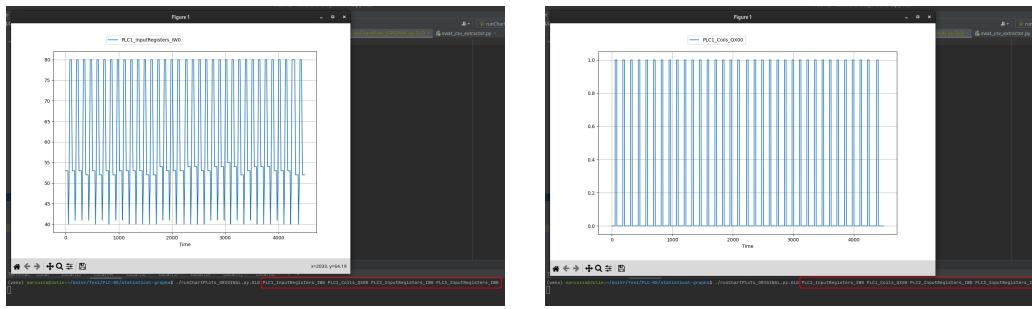

1111 In short, there is no possibility to analyze only a subsystem and thus
1112 make the analysis faster and more understandable. Moreover, a data
1113 gathering can take up to days, and the analyst/attacker may need to
1114 make an analysis of the system isolating precise time ranges, ignor-
1115 ing everything that happens before and/or after: all of this, with the
1116 tool we have seen, cannot be done.

1117 ***Second limitation*** Regarding the additional attributes, looking at the code
1118 of the script that performs the enrichment, we observed that **some at-**
1119 **tributes were manually inserted** after the merging phase: we are re-
1120 ferring in particular to the attributes PLC x _Max_safety and PLC x _Min_safety,
1121 whose references were moreover hardcoded into the script, and the
1122 *slope* whose calculation method we mentioned in the previous para-
1123 graph about the testbed limitations.

1124 In the end, only the attribute *prev* related to the value at the previous
1125 point of the detection is inserted automatically for all registers, more-
1126 over without the possibility to choose whether this attribute should
1127 be extended to all registers or only to a part.

1128 **Graphs and Statistical Analysis** Describing the behavior of graphical
1129 analysis in Section 3.2.3 we had already mentioned that only one register

1130 plot at a time was shown and not, for example, a single window containing
 1131 the charts of all registers entered by the user as input from the com-
 1132 mand line, such as in Figure 3.5. Figure 3.8 shows the actual behavior
 1133 of graphical analysis: note that although we have specified four registers
 1134 (highlighted in red in the figures) as command-line parameters, only one
 1135 at a time is shown and it is necessary to close the current chart in order to
 1136 display the next one.

(a) Chart for PLC1_InputRegisters_IW0

(b) Chart for PLC1_Coils_QX00

Figure 3.8: Behavior of the Graph Analysis on the Ceccato et al.'s tool

1137 ***First limitation*** While displaying charts for individual registers still pro-
 1138 vides useful information about the system such as the distinction
 1139 between actuators and measurements and the general trend of the
 1140 latter, single display does not allow one to catch, or at least makes it
 1141 difficult, the relationship that exists between actuators and measure-
 1142 ments, where it exists, because a view of the system as a whole is
 1143 missing.

1144 In this way, the risk is to make conjectures about the behavior of the
 1145 system that may prove to be at least imprecise, if not inaccurate.

1146 ***Second limitation*** On the other hand, regarding the statistical analysis,
 1147 two observations need to be made: the first is that for the given sys-
 1148 tem, I personally was unable to appreciate the usefulness of the gen-
 1149 erated histogram in Figure 3.3b, as it does not provide any particular
 1150 new information that has not already been obtained from the graph-
 1151 ical analysis (except maybe something marginal); the second obser-

52 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

1152 vation pertains to the presentation of statistical information obtained
1153 from the histogram plot. In certain cases, the histogram plot itself
1154 can overshadow the displayed statistical information. These statis-
1155 tics are actually shown on the terminal from which the script is exe-
1156 cuted. However, to an inattentive or unfamiliar user, these statistics
1157 may be mistaken for debugging output or warnings, as they coin-
1158 cide with the display of the histogram plot window, which takes the
1159 focus (see Figure 3.9).

1160

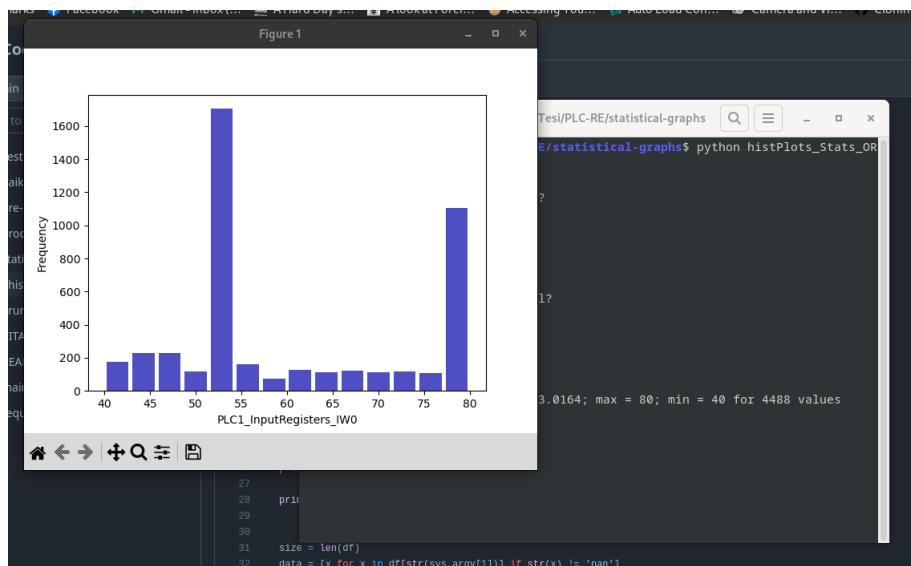

Figure 3.9: Histogram plot overshadowing statistical information shown on the terminal window in the background

1161

In general, however, little statistical information is provided.

1162 **Business Process Mining and Analysis** Concerning the data mining,
1163 this is a purely *ad hoc solution*, designed to work under special conditions:
1164 first, the timestamped dataset of the physical process and the one obtained
1165 after the packet sniffing operation of Modbus traffic on the network need
1166 to be synchronized and have the same granularity, in this case one event
1167 per second.

1168 It is relatively easy, therefore, to find correspondences between Modbus

1169 commands sent over the network and events occurring on the physical
1170 system, such as state changes in actuators, due in part to the fact that the
1171 number of communications over the network is really small (see Section
1172 3.2.1).

1173 ***First limitation*** In a real system, network communications are much more
1174 numerous and involve many more devices even in the same second:
1175 finding the exact correspondence with what is happening in the cy-
1176 ber physical system becomes much more difficult.

1177 Since this is, as mentioned, an *ad hoc* solution, only the Modbus pro-
1178 tocol is being considered: as widely used as this industrial protocol
1179 is, other protocols that are widely used [53] such as EtherNet/IP (see
1180 Section 2.2.6.2) or Profinet should be considered in order to extend
1181 the analysis to other industrial systems that use a different commu-
1182 nication network.

1183 ***Second limitation*** The other limiting aspect of the business process min-
1184 ing phase is the **process mining software** used to generate the ac-
1185 tivity diagram. As mentioned in Section 3.2.5, the process mining
1186 software used by Ceccato et al. is **Disco**: this is commercial soft-
1187 ware, with an academic license lasting only 30 days (although free of
1188 charge), released for Windows and MacOS operating systems only,
1189 which makes its use under Linux systems impossible except by us-
1190 ing emulation environments such as Wine.

1191 For what is my personal vision and training as a computer scientist,
1192 it would have been preferable to use a *cross-platform, freely licensed*
1193 *open source* software alternative to Disco: one such software could
1194 have been **ProM Tools** [54], a framework for process mining very
1195 similar to Disco in functionality, but fitting the criteria just described,
1196 or use Python libraries such as **PM4PY** [55], which offer ready-to-use
1197 algorithms suitable for various process mining needs.

54 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

1198 **Invariants Inference and Analysis** The limitation in this case is principally Daikon: this software is designed to compute the invariants of a software from its live execution or from a file containing its execution flow, not to find the invariants of a cyber physical system. Since there are currently no better consolidated alternatives for inferring invariants, however, an attempt was still made to use Daikon as best as possible.

```

Figure 3.10: Example of Daikon's output

1204 **First limitation** The biggest problem with Daikon applied to the computation of invariants of an industrial system is the difficult reading of the resulting output: the software in fact returns a very long list 1205 of invariants, one invariant per line, many of no use and without 1206 correlating invariants that may have common features or deriving 1207 1208

1209 additional information from them. The process of screening and rec-
1210ognizing the significant invariants, as well as the correlation between
1211them, must be done by a human: certainly not an easy task given the
1212volume of invariants one could theoretically be faced with (hundreds
1213and hundreds of invariants). An example of Daikon's output can be
1214seen in Figure 3.10.

1215 **Second limitation** The bash script used in this phase of the analysis does
1216not help at all in deriving significant invariants more easily: it merely
1217launches Daikon and saves its output to a text file by simply redirect-
1218ing the stdout to file. No data reprocessing is done during this step.
1219In addition, if a condition is to be specified to Daikon before perform-
1220ing the analysis, it is necessary each time to edit the .spinfo file by
1221manually entering the desired rule, an inconvenient operation when
1222multiple analyses are to be performed with different conditions each
1223time.

1224 Table 3.1 provides a summary of the limitations discussed regarding the
1225 Ceccato et al. framework:

| Phase | Limitations |
|--------------------------------|---|
| Testbed | <ul style="list-style-type: none">- Oversimplified model compared other testbeds- Physics of the liquid not considered: this causes data perturbation. |
| Pre-processing | <ul style="list-style-type: none">- It is not possible to select a subsystem by (groups of) PLCs or by time range- Some additional attributes are manually inserted into dataset. |
| Graphical/Statistical Analysis | <ul style="list-style-type: none">- Only one chart at the time is displayed: difficulty in capturing the relationship between actuators and sensors.- Statistical Analysis provides little information |

56 3.2 Ceccato et al.'s black-box dynamic analysis for water-tank systems

| | |
|---------------------------|--|
| Business Process Analysis | - Ad hoc solution designed to work under special conditions - Use of commercial software for process mining |
| Invariant Analysis | - Reading output is challenging - Script for analysis merely launches Daikon without reprocessing outcomes |

Table 3.1: Summary table of Ceccato et al. framework limitations

Extending and Generalizing Ceccato et al.'s Framework

1226 IN Chapter 3, we presented the state of the art of *process comprehension*
1227 of an Industrial Control System (ICS) with a focus on the methodology
1228 proposed by Ceccato et al. [9][Section 3.2], explaining what it consists of,
1229 its practical application on a testbed, and most importantly highlighting
1230 its limitations and critical issues (see Section 3.2.7).

1231 In this chapter we will present a **proposal to improve the methodology**
1232 seen in the previous chapter, addressing most of the critical issues (or
1233 at least trying to do so) described in Section 3.2.7 by almost completely
1234 rewriting the original framework, enhancing its functionalities and in-
1235 serting new ones where possible, while preserving its general structure
1236 and approach. Indeed, the system analysis will encompass the same **four**
1237 **phases** as the original methodology (Data Pre-processing, Graphs and Sta-
1238 tistical Analysis, Business Process Mining and Analysis, and Invariant In-
1239 ference and Analysis). In addition to these phases, a **fifth phase** dedicated
1240 exclusively to **network traffic analysis** will be introduced. Each phase of
1241 the original methodology will undergo thorough revision to enhance the
1242 understanding of the industrial system being analyzed and its behavior,
1243 aiming to provide a more complete and coherent process comprehension.
1244 This revision aims to enrich the analysis process, making it more robust

1245 and transparent.

1246 Please note that our proposals do not include improvements to the data
1247 gathering phase. This decision is solely because the new framework will
1248 not be tested on the same case study used by Ceccato et al. (Section 3.2.1),
1249 but rather on a different case study known as the iTrust SWaT system [36].
1250 iTrust has already provided some datasets that contain the execution trace
1251 of the physical system and the network traffic scan for this case study. In
1252 contrast to the case study conducted by Ceccato et al., the iTrust SWaT
1253 system is not simulated but rather a **real-world system**. This distinction
1254 is important as it introduces additional complexities and considerations
1255 when analyzing and interpreting the data.

1256 **Outline** The upcoming sections provide an outline of what to expect:

- 1257 • **Section 4.1** will introduce a **novel framework** that we have devel-
1258 oped to address the limitations of Ceccato et al.'s framework. Sec-
1259 tion will provide a brief overview of the framework's features and
1260 structure;
- 1261 • in **Section 4.2** the **features of our framework** will be demonstrated
1262 through their application to the different steps of the methodology.
1263 Practical examples will be used to illustrate the functionality of the
1264 framework. To facilitate this, we will utilize a more complex and
1265 detailed testbed compared to the one employed by Ceccato et al.

1266 4.1 The Proposed New Framework

1267 In our version of the framework we decided to follow a few design
1268 choices:

- 1269 1. it must be implemented in a **single programming language**;
- 1270 2. it must be **as independent as possible of the system** to be analyzed;

1271 3. It must provide greater **flexibility and ease of use** at every stage.

1272 In the following, we discuss these three features in more detail.

1273 **Single Programming Language** The implementation of Ceccato et al.'s tool
1274 involved the use of different programming languages for each of the
1275 phases, ranging from Python to Java, and even including Bash script-
1276 ing.

1277 However, we believe that this heterogeneity introduces challenges
1278 in terms of user-friendliness and intuitiveness. It becomes more dif-
1279 ficult for users to navigate and operate the tool effectively. Fur-
1280 thermore, the utilization of multiple technologies complicates code
1281 maintenance and the addition of new features, especially when man-
1282 aged by a single person who may have expertise in only one lan-
1283 guage while being less familiar with others.

1284 Considering these factors, we have made the decision to adopt a
1285 single programming language for the framework to ensure homo-
1286 geneity, simplify usability, and facilitate code maintenance for fu-
1287 ture users. Python has been chosen as the language of choice due
1288 to its simplicity, readability, versatility, and powerfulness. Addition-
1289 ally, Python benefits from a vast ecosystem of libraries and packages
1290 that cater to various requirements, making it a suitable choice for our
1291 framework.

1292 **System Independence** One of the significant limitations we identified in
1293 Ceccato et al.'s tool, as highlighted in Section 3.2.7, is its **strong de-**
1294 **pendence on the specific testbed** being used. This means that the
1295 tool lacks the flexibility to configure parameters for analyzing differ-
1296 ent industrial systems.

1297 To address this limitation and achieve system independence, we have
1298 made a crucial improvement in our framework. We have introduced
1299 a comprehensive configuration file called *config.ini* that allows users
1300 to customize all the necessary parameters for analyzing the targeted

1301 system. This general configuration file eliminates any references to
1302 hardcoded variables or values found in the Ceccato et al.'s tool, pro-
1303 viding users with the flexibility to tailor the analysis according to
1304 their specific requirements.

1305 **Flexibility and Ease on Use** The lack of flexibility and ease of use in a tool
1306 can be a significant disadvantage, as it hampers its effectiveness and
1307 makes it difficult for users to achieve their desired outcomes. Cec-
1308 cato et al.'s tool was affected by these limitations, as it required users
1309 to run scripts from the command line without sufficient options or
1310 parameters for customizing the analysis. Consequently, the tool fell
1311 short in terms of user-friendliness and failed to provide the neces-
1312 sary flexibility to accommodate specific user requirements.

1313 To settle these issues, we enhanced the command-line interface in the
1314 proposed framework by adding new options and parameters. These
1315 new features provide the user with greater flexibility, enabling to
1316 specify parameters and options that allow for more in-depth anal-
1317 ysis and focused results analyzing data more effectively and effi-
1318 ciently. With these enhancements, the framework has become more
1319 user-friendly, reducing the learning curve and making it more acces-
1320 sible to a wider range of users.

1321 This, in turn, makes the framework more valuable and useful, in-
1322 creasing its adoption and effectiveness across a range of industrial
1323 control systems and applications.

1324 Moreover, with new options and parameters users can now access a
1325 range of customizable options and parameters, making the tool more
1326 intuitive and user-friendly.

1327 Overall, the enhancements made to the framework represent a significant
1328 step forward in making it more effective, efficient, and user-friendly.

1329 **4.1.1 Framework Structure**

1330 The proposed framework follows a similar structure to the original
 1331 tool, with a division into five main directories representing different phases
 1332 of the analysis: **data pre-processing, graphs and statistical analysis, pro-**
1333 cess mining, and invariant analysis. A new phase is added compared to
 1334 the original, concerning the **analysis of the network traffic.** These directo-
 1335 ries contain the corresponding Python scripts responsible for performing
 1336 the analysis, along with any necessary subdirectories and input/output
 1337 files to ensure the proper functioning of the framework.

Listing 4.1: Novel Framework structure and Python scripts

1358 The *config.ini* file is located in the root directory of the framework. This
 1359 file holds significant importance as it grants the framework independence
 1360 from the industrial control system being analyzed. Within this file, users
 1361 have the opportunity to configure various general parameters and op-
 1362 tions. These include specifying file paths for reading or writing files, as

1363 well as options related to specific analysis phases.

1364 The file is organized into sections, with each section dedicated to a spe-
1365 cific aspect of the configuration. These sections contain user-customizable
1366 parameters that are later referenced within the Python scripts comprising
1367 the framework. Sections of *config.ini* are:

- 1368 • [PATHS]: defines general paths such as the project root directory;
- 1369 • [PREPROC]: includes parameters needed for the **pre-processing phase**,
1370 like the directory containing the raw datasets of the individual PLCs
1371 and *granularity* for the slope calculation. The granulariy is given in
1372 terms of the time interval over which the slope is calculated;
- 1373 • [DATASET]: defines settings and parameters used during the **dataset**
1374 **enrichment** stage, for example the additional attributes;
- 1375 • [DAIKON]: defines parameters needed for **invariant analysis** with
1376 Daikon, e.g. directories and files containing the outcomes of the anal-
1377 ysis;
- 1378 • [MINING]: contains parameters used during the **process mining**
1379 phase, such as data directory;
- 1380 • [NETWORK]: includes specific settings for extracting the data ob-
1381 tained from the packet sniffing phase on the ICS network and con-
1382 verting it to CSV format. It also defines the **network protocols** that
1383 are to be analyzed.

1384 4.1.2 Python Libraries and External Tools

1385 As the framework has been developed entirely in Python, the objec-
1386 tive was to minimize reliance on external tools and instead integrate vari-
1387 ous functionalities within the framework itself. The aim was to make the
1388 framework independent from external software. The only remaining ex-
1389 ternal tool from the Ceccato et al. tool is Daikon. This choice was made

1390 because there is currently no better alternative or Python package avail-
1391 able that offers the same functionalities as Daikon.

1392 Instead, the framework extensively utilizes Python libraries for han-
1393 dling various functionalities and input data. The core libraries on which
1394 the framework relies are:

- 1395 • **Pandas**, also used in the Ceccato et al.'s tool for dataset management,
1396 but whose use here has been deepened and extended
- 1397 • **NumPy**, often used together with Pandas to perform some opera-
1398 tions to support it;
- 1399 • **MatPlotLib**, for managing and plotting graphical analysis;
- 1400 • other scientific libraries such as **SciPy**, **StatsModel** [56] and **Net-**
1401 **workX** [57], for mathematical, statistical and analysis operations on
1402 the data;
- 1403 • **GraphViz**, for the creation of activity diagrams in the process mining
1404 phase.

1405 Having now seen the structure of the framework, in the next sections we
1406 will go into more detail describing our proposal.

1407 4.2 Analysis Phases

1408 In this section, the behavior of the proposed framework throughout the
1409 various analysis phases of the methodology will be illustrated. Here is a
1410 brief **outline** of the content covered in this section:

- 1411 • **Section 4.2.1:** this section will present the **testbed** used to demon-
1412 strate examples of the framework's application;
- 1413 • **Section 4.2.2:** the introduction of the new **network traffic analysis**
1414 phase (*Phase 0*) will be discussed. This phase aims to understand the
1415 structure of the industrial system's network and analyze its commu-
1416 nication patterns;

- **Section 4.2.3:** the **pre-processing** phase (*Phase 1*) will be presented, consisting of two parts: dataset merging and enrichment, followed by a preliminary analysis of the resulting dataset;
 - **Section 4.2.4:** this section focuses on the **Graphs and Statistical Analysis** phase (*Phase 2*). It will demonstrate the extraction of valuable information from the system by analyzing graphs that represent the behavior of registers over time;
 - **Section 4.2.5:** the **Invariant Inference** phase (*Phase 3*) will be explored. This phase involves deriving system information based on discovered invariants through the use of Daikon. Two examples of semi-automatic analysis will be showcased;
 - **Section 4.2.6:** the **Business Process Mining** phase (*Phase 4*) will be covered. This phase aims to gain an overview of the system's behavior and extract additional information through process mining techniques.

¹⁴³² 4.2.1 A Little Testbed: Stage 1 of iTrust SWaT System

1433 Before we proceed with presenting the analysis steps of the proposed
1434 framework, let us introduce the testbed that will serve as an illustration for
1435 practical examples, demonstrating the effectiveness of our methodology
1436 and the potential of the framework. This testbed corresponds to Stage 1 of
1437 the iTrust SWaT (Secure Water Treatment) system [36]. The selection of this
1438 testbed is intentional, as it serves as a precursor to the comprehensive case
1439 study we will be addressing in the upcoming chapters. The iTrust SWaT
1440 system offers elements of greater complexity compared to the individual
1441 stages of the Ceccato et al. testbed.

1442 The testbed comprises several components, including:

- a **tank**, which serves as the main element of interest;

- 1444 • a PLC responsible for monitoring and controlling the operations within
1445 the stage;
- 1446 • **two sensors** that provide readings of the water level within the tank
1447 and the incoming flow. These sensors are identified as LIT101 and
1448 FIT101 in the PLC registers;
- 1449 • **three actuators**, namely a valve and two pumps. These actuators
1450 regulate the level within the tank by controlling the inflow and out-
1451 flow of the liquid. These sensors are identified as MV101 (valve), P101
1452 and P101 (pumps) in the PLC registers.

1453 Despite its moderate complexity, this testbed provides an ideal plat-
1454 form for presenting straightforward and concise examples of the frame-
1455 work's behavior. It enables us to effectively demonstrate the potential
1456 of the framework and facilitate a deeper understanding of its underlying
1457 methodology.

1458 4.2.2 Phase 0: Network Analysis

1459 The objective of the network analysis presented in this section is to offer
1460 users valuable information regarding the communication process within
1461 an industrial control system and a broader perspective on network com-
1462 munications, delving into previously unexplored aspects of the system.
1463 These additional dimensions provide a deeper understanding of the sys-
1464 tem's behavior and characteristics. This analysis aims to provide users
1465 with an overview of the communication between PLCs at level 1 (see Fig-
1466 ure 2.1), as well as the communication between PLCs and devices at higher
1467 levels such as HMIs and Historian servers (see Section 2.1 for ICSs archi-
1468 tecture). This also allows us to have a better understanding of the system
1469 architecture and network topology. The analysis focuses on industrial pro-
1470 tocols used and the information exchanged.

1471 By reconstructing the network communication structure using data ob-
1472 tained from the network traffic sniffing process, users can gain a compre-
1473 hensive understanding of the behavior of the underlying industrial sys-

1474 tem. This knowledge can then be utilized to **plan a strategy** for analyzing
1475 the physical processes within the system.

1476 **4.2.2.1 Extracting Data from PCAP Files**

1477 The initial step involves extracting the desired information from the
1478 PCAP files that contain the captured network traffic. This includes details
1479 such as the source IP address, destination IP address, protocol used, and
1480 the type of request made (e.g., Read/Write, Request/Response). The ex-
1481 tracted data is then converted into a more convenient CSV format. This
1482 extracted data serves as the foundation for the subsequent phase.

1483 In the latter part of this phase, the extracted data is utilized to generate
1484 the network schema. The network schema provides a visual representa-
1485 tion of the connections and relationships within the network, showcasing
1486 the communication patterns between different components. This schema
1487 helps in understanding the overall structure and behavior of the industrial
1488 control system.

1489 To accomplish the extraction of data from the PCAP files, a Python
1490 script called `export_pcap_data.py` is employed. This script, originally de-
1491 signed for the business process phase, is located in the directory
1492 `$(project_dir)/network-analysis` and accepts the following options as
1493 command-line arguments:

- 1494 • **-f or --filename:** allows the user to specify a single PCAP file to be
1495 passed as input to the script. The user can provide the complete file
1496 path of the PCAP file as an argument;
- 1497 • **-m or --mergefiles:** enables the merging of multiple PCAP files. In
1498 this scenario, the files should be located within the directory speci-
1499 fied by the `pcap_dir` directive in the `config.ini` configuration file and
1500 the user does not have to provide the path to each PCAP file;
- 1501 • **-d or --mergedir:** allows for specifying the directory that contains the
1502 PCAP files to be automatically imported into the script and merged.

1503 This ensures that all the PCAP files within the specified directory will
1504 be processed by the script without the need for manual selection or
1505 input.

- 1506 • **-s or --singledir:** operates differently from the previous option men-
1507 tioned. This option enables the extraction of data from each individ-
1508 ual PCAP file within the specified directory. The extracted data is
1509 then saved in separate CSV datasets, which are stored in the direc-
1510 tory specified by the `split_dir` directive in the `config.ini` file. This
1511 functionality proves useful when dealing with exceptionally large
1512 PCAP files, where merging them together for export might consume
1513 significant time and resources. By utilizing this option, the extrac-
1514 tion procedure becomes lighter and more manageable. The extracted
1515 data in separate CSV files can be utilized in the later stages of the
1516 Network Analysis process;
- 1517 • **-t or --timerange:** this functionality enables users to specify a specific
1518 time period within the PCAP files from which they wish to extract
1519 relevant information.

1520 Unless the `-s` option is explicitly specified, the results of data extraction
1521 and export will be saved to a single CSV dataset within the
1522 `$(project_dir)/network-analysis/data` directory. The default file name
1523 for this output file is determined by the `pcap_export_output` directive spec-
1524 ified in the `config.ini` file. In addition, by utilizing the `protocols` and
1525 `ws_<protocol>_field` directives, user can configure the network protocols
1526 to be searched within the PCAP files. Furthermore, user can specify the
1527 relevant Tshark/Wireshark fields to extract for the specified protocols set
1528 in the `protocols` directive.

1529 After obtaining the extracted data, it is possible to proceed with the
1530 second part of the network analysis.

1531 **4.2.2.2 Network Information**

1532 During this stage, the exported CSV data is processed to derive valua-
1533 able information regarding network communications and the structure of
1534 the network itself. The objective is to identify and establish relationships
1535 between IP addresses present on the network, thereby determining the
1536 sources and destinations of communications. Furthermore, the analysis
1537 detects the protocols used for each communication and quantifies the var-
1538 ious types of requests made.

1539 This information is then transformed into a **graph representation of**
1540 **the network** (or subnetwork, if specified). In this graph, devices are repre-
1541 sented as nodes labeled with their IP addresses, while edges represent the
1542 incoming and outgoing communications of these devices, along with the
1543 corresponding information.

1544 To ensure comprehensibility, the analysis also provides users with **textual**
1545 **information** containing the same details as the graph representation. This
1546 text-based information serves as an alternative for cases where the graph
1547 may become complex to interpret, particularly when numerous edges con-
1548 nect nodes and result in a high volume of network requests.

1549 This textual information is saved to another CSV file, enabling offline ref-
1550 erence or potential future utilization. By having this file available, users
1551 can access the network analysis results in a structured format for further
1552 analysis or documentation purposes.

1553 The Python script `networkAnalysis.py` in the `$(project_dir)/network-analysis`
1554 directory manages this phase of the analysis. The script can be executed
1555 with the following parameters:

- 1556 • **-f** or **--filename**: used to specify the CSV dataset containing the net-
1557 work data exported in the previous step. The dataset should be lo-
1558 cated in the directory `$(project_dir)/network-analysis/data`;
- 1559 • **-D** or **--directory**: used to specify the directory that contains the CSV
1560 datasets obtained using the `-s` option of the Python script `export_pcap_data.py`.

1561 By passing this parameter, the script will automatically merge the
1562 datasets and proceed with the analysis of the data contained within
1563 them;

- 1564 • **-s or --srcaddr:** allows for specifying the source IP address for which
1565 you wish to display the incoming and outgoing communications. By
1566 providing the source IP address as an argument, the script will focus
1567 on showcasing the communications associated with that particular
1568 IP address;
- 1569 • **-d or --dstaddr:** enables the user to specify the destination IP address
1570 for which you want to display the incoming and outgoing communi-
1571 cations. By providing the destination IP address as an argument, the
1572 script will concentrate on presenting the communications associated
1573 with that specific IP address.

1574 The parameters related to IP addresses, including source and destina-
1575 tion, are optional. It is possible to specify either one of them individually.
1576 For instance, if the user specifies only the source IP address, the script will
1577 display the network nodes with which it communicates on the outgoing
1578 side, along with the corresponding generated traffic. Similarly, if only the
1579 destination IP address is specified, the script will showcase the network
1580 nodes communicating with it on the incoming side, along with the rele-
1581 vant traffic data.

1582 During the analysis, the script identifies and displays the IP addresses
1583 present in the network as output for the user's reference. This allows the
1584 user to select specific IP addresses from the command line for a more fo-
1585 cused analysis, such as choosing a subnet of interest. Additionally, the
1586 script detects and tracks distinct communications between pairs of PLCs,
1587 keeping a record of the number of these communications.
1588 The result of the analysis is a graph representation of the network (or sub-
1589 network) to be analyzed. An example of such a graph can be seen in Figure
1590 4.1.

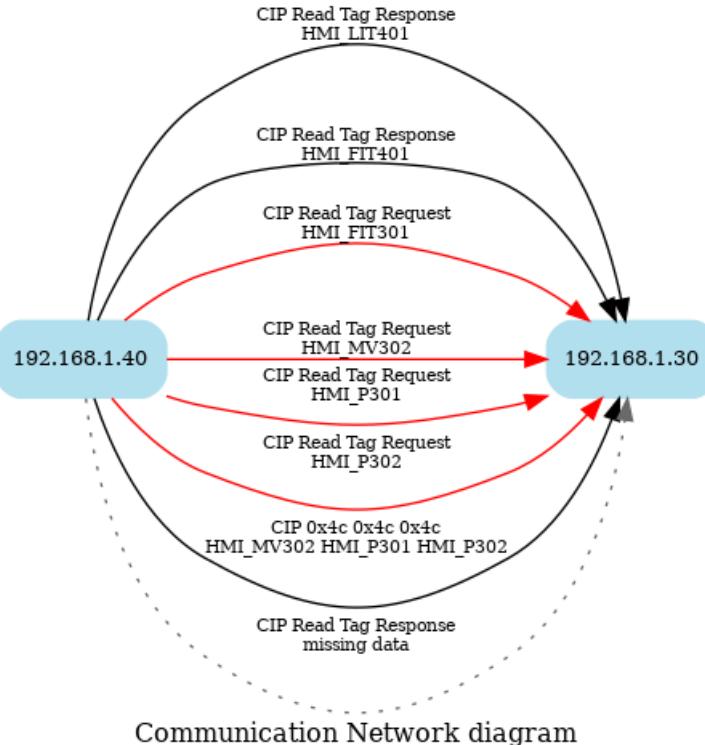

Figure 4.1: Network Communications between 192.168.1.40 (Source) and 192.168.1.30 (Destination)

1591 The graph illustrates the network communications between the source
 1592 IP address 192.168.1.40 and the destination IP address 192.168.1.30. Each
 1593 arrow represents a communication between these IP addresses, showcas-
 1594 ing the flow and direction of the interactions. The red arrows indicate re-
 1595 quests initiated by the source IP address towards the destination IP, while
 1596 the black arrows represent responses sent by the source IP in response
 1597 to previous requests made by the destination IP. The gray dotted arrows
 1598 represent responses for which the corresponding request is missing or un-
 1599 available for some reason. Overall, the graph distinguishes the different
 1600 types of communications and provides insights into the request-response
 1601 dynamics between the source and destination IP addresses. The graph is
 1602 automatically generated and saved within the
 1603 `$(project_dir)/network-analysis/data` directory.

1604 In terms of the textual output, we can observe how the same data is
 1605 represented. The communications exchanged between the two PLCs are
 1606 displayed more prominently, allowing for a clearer understanding. Unlike
 1607 the graph, the textual representation includes a column on the right-hand
 1608 side, indicating the number of communications for each type of request.
 1609 This provides a more distinct perspective on the network behavior within
 1610 an industrial control system that utilizes, in this case, the CIP protocol for
 1611 its communications.

| src | dst | protocol | service_detail | register | |
|--------------|--------------|----------------|-------------------|-----------------------------|-------|
| 192.168.1.40 | 192.168.1.30 | CIP | Read Tag Response | HMI_LIT401 | 11249 |
| | | | | HMI_FIT401 | 10539 |
| | | | Read Tag Request | HMI_FIT301 | 8031 |
| | | | | HMI_MV302 | 7209 |
| | | | | HMI_P301 | 7115 |
| | | | | HMI_P302 | 7040 |
| | | 0x4c 0x4c 0x4c | | HMI_MV302 HMI_P301 HMI_P302 | 1 |
| | | | Read Tag Response | missing data | 1 |

Figure 4.2: Network Communications between 192.168.1.40 (Source) and 192.168.1.30 (Destination) in textual mode

1612 As previously mentioned, the textual data is stored in a CSV dataset
 1613 located in the \$(project_dir)/network-analysis/data directory.

1614 4.2.3 Phase 1: Data Pre-processing

1615 *Data Pre-processing phase* is probably the most delicate and significant
 1616 one: depending on how large the industrial system to be analyzed is, the
 1617 data collected, and how it is enriched using the additional attributes, the
 1618 subsequent system analysis will provide more or less accurate outcomes.

1619 The Ceccato et al.'s tool has several limitations, particularly at this
 1620 stage. It does not allow for the isolation of a subsystem, either in terms
 1621 of time or the number of PLCs to be analyzed. The system is considered as
 1622 a whole without the ability to focus on specific subsystems. Additionally,
 1623 many of the additional attributes had to be manually added, and for the
 1624 ones entered automatically, there is no way to specify the register type to

1625 associate them with.

1626 The combination of these limitations, along with the presence of hard-
1627 coded references to attributes and registers in the tool's code, makes the
1628 analysis of the system more challenging. Furthermore, it compromises the
1629 accuracy and reliability of the obtained results in terms of both quantity
1630 and quality.

1631 In the proposed framework, these issues have been addressed by in-
1632 corporating new features.

1633 *Firstly*, the framework allows for the **selection of a subsystem from the**
1634 **command line** based on both temporal criteria and the specific PLCs to be
1635 included. This enables more focused and targeted analysis.

1636 *Secondly*, we have **revamped the process of enriching** the resulting dataset
1637 by eliminating manual entry of additional attributes. Instead, users now
1638 have the flexibility to determine the type of additional attribute to asso-
1639 ciate with a specific register.

1640 *Thirdly*, after the pre-processing stage, a **preliminary analysis** can be con-
1641 ducted on the resulting dataset. This analysis aims to identify the reg-
1642 isters that are associated with actuators, measurements, and hardcoded
1643 setpoints or constants. It provides insights into the dataset and helps in
1644 refining the enrichment step. The parameters for this analysis can be con-
1645 figured in the *config.ini* file, allowing for customization and fine-tuning of
1646 the process.

1647

1648 In the upcoming sections, we will delve into a more comprehensive ex-
1649 amination of the achievements made in this phase.

1650 4.2.3.1 Subsystem Selection

1651 In Ceccato et al.'s tool, the datasets for each individual PLC in CSV for-
1652 mat were required to be placed in a specific directory that was hardcoded
1653 in the script. The script would then merge and enrich these datasets to
1654 generate a single output dataset representing the complete process trace
1655 of the industrial system. However, the script did not provide options to

1656 select specific PLCs for analysis or define a temporal range for analysis.
 1657 This lack of flexibility made the analysis more complex, especially when
 1658 dealing with *transient states* (i.e., general states in which the industrial sys-
 1659 tem is still initializing before actually reaching full operation) or when fo-
 1660 cusing on specific parts of the industrial system during certain periods of
 1661 interest. The fixed dataset structure also may increase the number of vari-
 1662 ables that could be analyzed.
 1663 Furthermore, the tool in question did *not* allow for specifying an output
 1664 CSV file to save the resulting dataset. Each dataset creation and enrich-
 1665 ment operation would overwrite the previous file, making it inconvenient
 1666 for comparisons between different execution traces unless the files were
 1667 manually renamed.

1668 The proposed framework addresses these issues by introducing im-
 1669 provements. First of all, in the general *config.ini* file there are some general
 1670 default settings about paths, and among them the one concerning the di-
 1671 rectory where to place the datasets to be processed. In addition to this
 1672 option, there are other ones that define further aspects related to the oper-
 1673 ations performed in this phase. Listing 4.2 shows the settings in question:

```
1674 [PATHS]
1675 root_dir = /home/marcuzzo/UniVr/Tesi
1676 project_dir = %(root_dir)s/PLC-RE
1677 net_csv_path = %(root_dir)s/datasets_SWaT/2015/Network_CSV
1678
1679 [PREPROC]
1680 raw_dataset_directory = datasets_SWaT/2015 # Directory
1681   ↪ containing datasets
1682 dataset_file = PLC_SWaT_Dataset.csv # Default output
1683   ↪ dataset
1684 granularity = 10 # slope granularity
1685 number_of_rows = 20000 # Seconds to consider
1686 skip_rows = 100000 # Skip seconds from beginning
```

Listing 4.2: Paths and parameters for the Pre-processing phase in config.ini file

1687 At the same time, the user has the option to specify these settings via the
 1688 command line using the new Python script called *mergeDatasets.py*, lo-

1689 cated in the pre-processing directory of the project. Any options provided
1690 through the command line will override the default settings specified in
1691 the *config.ini* file. These options are:

- 1692 • **-s or --skiprows:** initial transient period (expressed in seconds) to
1693 be skipped. This option is useful in case the system has an initial
1694 transient or the analyzer wishes to start the analysis from a specific
1695 point in the dataset;
- 1696 • **-n or --nrows:** time interval under analysis, expressed in terms of the
1697 number of rows in the dataset.
1698 This option makes a **selection** on the data of the dataset;
- 1699 • **-p or --plcs:** PLCs to be merged and enriched. The user can specify
1700 the desired PLCs by indicating the CSV file names of the associated
1701 datasets with no limitations on number.
1702 This option makes a **projection** on the data of the dataset.
- 1703 • **-d or --directory:** performs the merge and enrichment of all CSV files
1704 contained in the directory specified by user, overriding the default
1705 setting in *config.ini*. It is in fact the old functionality of the Ceccato
1706 et al.'s tool, maintained here to give the user more flexibility and
1707 convenience in case he wants to perform the analysis on the whole
1708 system. This is also the default behavior in case the -p option is not
1709 specified.
- 1710 • **-o or --output:** specifies the name of the file in which the obtained
1711 dataset will be saved. It must necessarily be a file in CSV format.
- 1712 • **-g or --granularity:** specifies a granularity (expressed in seconds)
1713 that will be used to calculate the measurement slope during the dataset
1714 enrichment phase. We will discuss this later in Section 4.2.3.2.

1715 **4.2.3.2 Dataset Enrichment**

1716 After a step in which a function is applied to each PLC-related dataset
 1717 to eliminate its unused registers within the system¹, the **dataset enrichment operation** is performed.
 1718

1719 This operation brings about several distinctions compared to the previous
 1720 version. Firstly, it is performed on each individual dataset instead
 1721 of the resulting dataset. Additionally, there are a greater number of attributes,
 1722 which are automatically calculated and added to the dataset by
 1723 the `mergeDatasets.py` script. Importantly, the configuration file `config.ini`
 1724 under the [DATASET] section allows users to determine which registers
 1725 should be assigned to these attributes.

1726 In Listing 4.3 we can see the list of additional attributes and how they
 1727 should be associated with the registers of the dataset:

```
1728 [DATASET]
1729 timestamp_col = Timestamp
1730 max_prefix = max_
1731 min_prefix = min_
1732 max_min_cols_list = lit|ait|dpit
1733 prev_cols_prefix = prev_
1734 prev_cols_list = mv[0-9]{3}|p[0-9]{3}
1735 trend_cols_prefix = trend_
1736 trend_cols_list = lit
1737 trend_period = 150
1738 slope_cols_prefix = slope_
1739 slope_cols_list = lit
```

Listing 4.3: config.ini parameters for dataset enriching

1740 In the following, we report a brief explanation of the parameters just seen:

1741 **timestamp_col** denotes the name of the column in the dataset that holds
 1742 the timestamp data. This parameter is significant not only in the
 1743 current phase but also in the Process Mining phase. In the Ceccato et

¹This becomes particularly relevant when conducting a Modbus register scan, where ranges of registers are examined. In this process, it is assumed that any unused registers hold a constant value of zero.

1744 al.'s work, this parameter was hardcoded and lacked configurability,
1745 leading to errors if the analyzed system changed.

1746 **max_prefix, min_prefix, max_min_cols_list** refer to any relative maximum
1747 or minimum values (*relative setpoints*) of one or more measures and
1748 that can be found and inserted as new columns within the dataset.
1749 The first two parameters indicate the prefix to be used in the column
1750 names affected by this additional attribute, while the third specifies
1751 of which type of registers we want to know the maximum and/or
1752 minimum value reached (several options can be specified using the
1753 logical operator | - or).

1754 If, for example, we want to know the maximum value of the regis-
1755 ters associated with the tanks, indicated in the iTrust SWaT system
1756 by the prefix LIT, we only need to specify the necessary parameter in
1757 the *config.ini* file, so `max_min_cols_list = lit`.

1758 The result will be to have in the dataset thus enriched a new column
1759 named `max_LIT101`.

1760 **prev_cols_prefix, prev_cols_list** refer to the values at the previous time
1761 instant of the registers specified in `prev_cols_list`. It is possible to
1762 specify registers using *regex*, as in the example shown. It may be use-
1763 ful in some cases to have this value available to check, for example,
1764 when a change of state of a single given actuator occurs. The behav-
1765 ior of these parameters is the same as described in the point above.

1766 **slope_cols_prefix, slope_cols_list** are related to the calculation of the
1767 slope of a specific register that contains numeric values (usually a
1768 measure), that is, its trend. Slope calculation makes little sense on
1769 booleans. The slope can be **ascending** (if its value is greater than
1770 zero), **descending** (if less than zero) or **stable** (if approximately equal
1771 to zero). We will delve into the details of slope calculation in the fol-
1772 lowing paragraph, as it pertains to the attributes `trend_cols_prefix`,
1773 `trend_cols_list`, and `trend_period`.

1774 Initially, the parameters for registers to be associated with each addi-

1775 tional attribute may be left blank, as we may not have prior knowledge
1776 about the system and are unsure about which registers correspond to ac-
1777 tuators, measurements, or other attributes. This information can be ob-
1778 tained from the preliminary analysis that follows the merging of datasets.
1779 The analysis, performed based on user's choice, provides indications on
1780 potential sensors, actuators, and other relevant information. These indica-
1781 tions help the user set the desired values in the *config.ini* file and refine the
1782 enrichment process by re-launching the `mergeDatasets.py` script.

1783 **Slope Calculation** The *slope* is an attribute that represents the **trend** of
1784 the measurement being considered. It is particularly useful, in our con-
1785 text, during the inference and invariant analysis phase to gather informa-
1786 tion about the trend under specific conditions. The slope can generally be
1787 classified as **increasing** ($slope > 0$), **decreasing** ($slope < 0$), or **stable** ($slope$
1788 $= 0$).

1789 Normally, the slope is calculated through a simple mathematical formula:
1790 given an interval a, b relative to the measurement l , the slope is given by
1791 the difference of these two values divided by the amount of time t that the
1792 measurement takes to reach b from a :

$$slope = \frac{l(b) - l(a)}{t(b) - t(a)}$$

1793 In the proposed framework, similar to the Ceccato et al.'s tool, this
1794 time interval (the granularity) can be adjusted to be either long or short.
1795 The choice of granularity depends on the desired accuracy of the slope
1796 calculation. A lower granularity will provide a slope that closely reflects
1797 the actual measurement trend, while a higher granularity will result in
1798 flatter slope data. Each time interval within which the measurement is
1799 divided corresponds to a slope value. These slopes are calculated and
1800 added as additional attributes in the dataset. Later on, these slope values
1801 are used to determine the trend of the measurement in specific situations
1802 or conditions.

1803 Calculating the slope directly from the raw measurement data can be
1804 a suitable approach for systems where the measurements are *not* heavily
1805 influenced by **perturbations**. Perturbations, such as liquid oscillations in
1806 a tank during filling and emptying phases, can lead to fluctuating read-
1807 ings of the level. In such cases, maintaining a low granularity can provide
1808 a more accurate calculation of the overall trend that closely aligns with
1809 the actual measurement trend. This situation occurs, for instance, in the
1810 testbed utilized by Ceccato et al.

1811

1812 However, if perturbations significantly affect the measurement readings,
1813 calculating the slope on individual time intervals may result in an inaccur-
1814 ate trend definition, irrespective of the chosen granularity. In such cases,
1815 the fluctuating nature of the measurements due to perturbations can intro-
1816 duce errors in the slope calculation, making it less reliable as an indicator
1817 of the actual trend.

1818

1819 Figure 4.3 demonstrates this assertion: the measurement, in blue, refers
1820 to the LIT101 tank of our testbed; in red, the slope calculation related to
1821 the measurement with three different granularities: 30 (Figure 4.3a), 60
1822 (Figure 4.3b) and 120 seconds (Figure 4.3c). It is noticeable that as the gran-
1823 ularity increases, the slope values flatten. Moreover, in the time interval
1824 between seconds 1800 and 4200, the level of LIT101 exhibits a predomi-
1825 nantly increasing trend, yet the calculated slope values fluctuate between
1826 positive and negative. Consequently, during the invariant analysis, the
1827 overall increasing trend may not be detected, resulting in a loss of infor-
1828 mation.

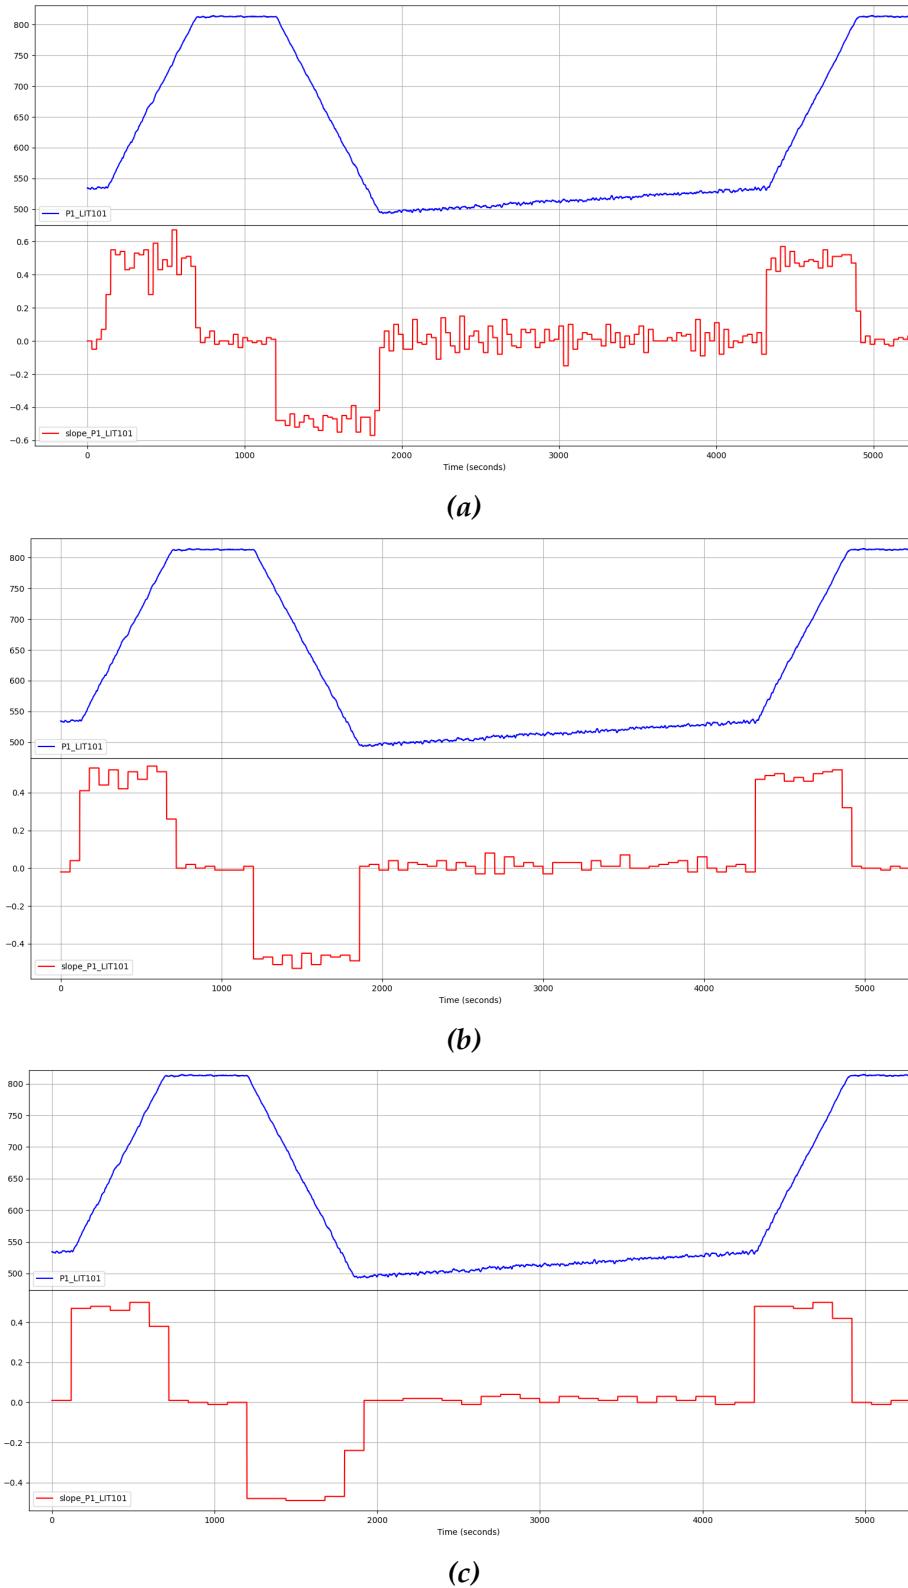

Figure 4.3: Slope comparison with granularity 30 (a), 60 (b) and 120 seconds (c)

1829 Ceccato et al.'s tool did not take into account the possibility of having
1830 strongly perturbed data, which presented a challenge that we needed to
1831 address in the development of the proposed framework.

1832 The solution to this problem involves applying techniques to reduce
1833 the "noise" in the data, aiming to achieve a more linear trend in the mea-
1834 surement curve. By minimizing the effects of perturbations, we can calcu-
1835 late slopes more accurately.

1836 There are various methods available for smoothing out noise in the data.
1837 In our framework, we focused on two commonly used approaches found
1838 in the literature: **polynomial regression** and **seasonal decomposition**. In
1839 addition to these two methods, we also explored the use of a **line simpli-
1840 fication algorithm**.

1841
1842 *Polynomial regression* [58] is a technique that allows us to create a filter to
1843 reduce the impact of noise on the data. By fitting a polynomial function
1844 to the measurements, we can obtain a smoother curve that captures the
1845 underlying trend while minimizing the effects of perturbations.

1846 *Seasonal decomposition* [59], specifically the part related to trending, is an-
1847 other method we explored. It involves decomposing the time series into
1848 different components, such as trend, seasonality, and residual. By isolat-
1849 ing the trend component, we can obtain a cleaner representation of the
1850 underlying pattern in the data.

1851 *Line simplification algorithms* [60] aim to reduce the complexity of a polyline
1852 or curve by approximating it with a simplified version composed of fewer
1853 points. By selectively removing redundant or less significant points, line
1854 simplification algorithms help reduce storage space and computational re-
1855 quirements while preserving the overall shape and characteristics of the
1856 original line.

1857 Regarding polynomial regression, we evaluated the use of the **Savitzky-**
1858 **Golay filter** [61] as a smoothing technique. For seasonal decomposition,
1859 we explored the **Seasonal-Trend decomposition using LOESS** (STL) method
1860 [62]. For the line simplification algorithm, we specifically considered the

1861 **Ramer-Douglas-Peucker (RDP) algorithm [63].**

1862

1863 Figure 4.4 shows a quick graphical comparison of these techniques com-
 1864 pared with the original data. The solution adopted is the *STL decomposition*
 1865 method, which effectively reduces noise compared to the Savitzky-Golay
 1866 filter. However, it should be noted that this method may introduce some
 1867 delay in certain parts of the data, as is typically observed in similar algo-
 1868 rithms. Despite its apparent effectiveness, the RDP algorithm fails to ac-
 1869 curately approximate sections where the measurement level remains rela-
 1870 tively stable. Consequently, it yields incorrect slope estimations, causing a
 1871 loss of valuable information about the system.

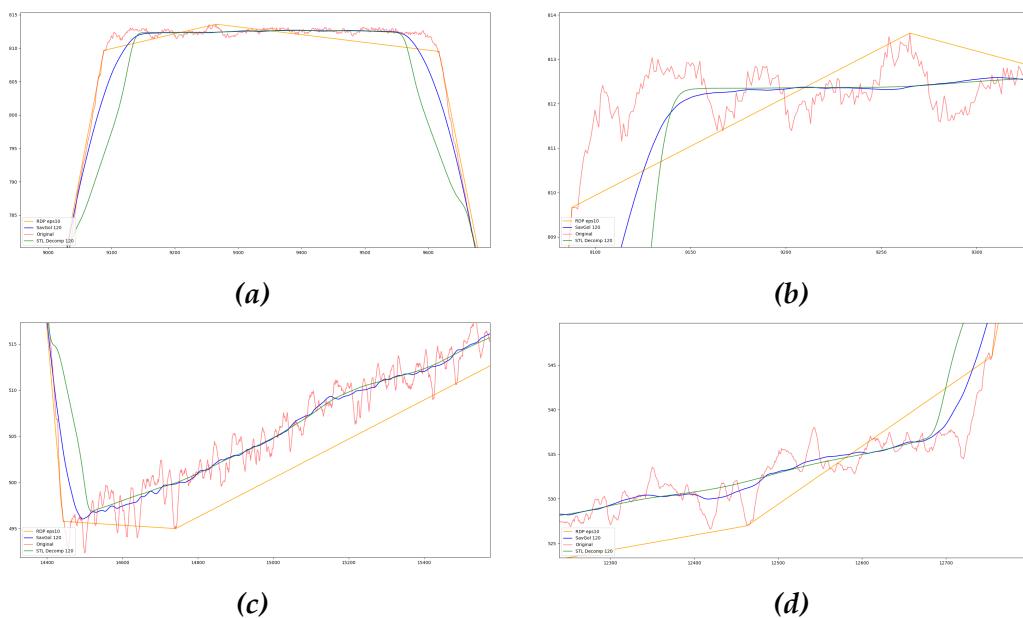

Figure 4.4: Savitzky-Golay filter (blue line), STL decomposition (green) and RDP algorithm (orange) comparison

1872

1873 By applying the STL decomposition, we observe a notable enhance-
 1874 ment in slope calculation even when using a low granularity. Figure 4.5
 1875 demonstrates that, with the same granularity as shown in Figure 4.3a, the
 1876 slope values, albeit exhibiting fluctuations, consistently align with the un-
 derlying trend of the data curve. The introduced lag resulting from the

1877 decomposition's periodicity is responsible for the observed delay.

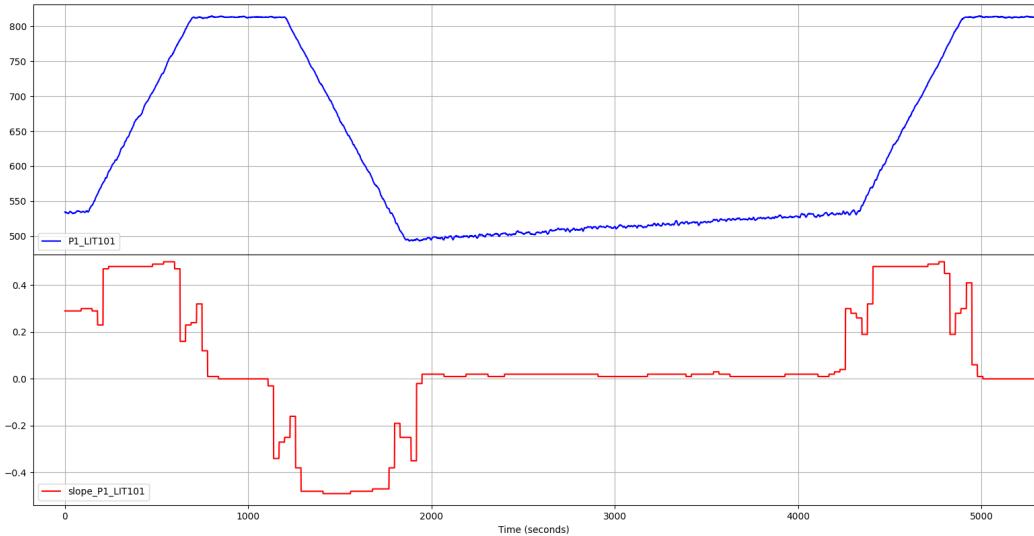

Figure 4.5: Slope after the application of the STL decomposition

1878 The periodicity, which defines the sampling time window for decomposi-
 1879 tion and the level of noise smoothing, can be configured using the `trend_period`
 1880 directive in the `config.ini` file.
 1881 During the slope calculation, the analysis will be performed on the data
 1882 from the additional measurement trend attributes specified in the `trend_cols_list`
 1883 directive of the configuration file, rather than on the original unfiltered
 1884 data.

1885 To ensure proper interpretation by Daikon, the decimal values repre-
 1886 senting the calculated slopes are converted into **three numerical values**:
 1887 -1, 0, and 1. These values correspond to *decreasing* (if the slope is less than
 1888 zero), *stable* (if it is equal to zero), and *increasing* (if it is greater than zero)
 1889 trends, respectively. Figure 4.6 displays the modified slopes along with
 1890 the curve obtained from the STL decomposition:

1891 4.2.3.3 Datasets Merging

1892 During this step, the datasets of the individual PLCs are merged, re-
 1893 sulting in two separate datasets. The first dataset is enriched with addi-

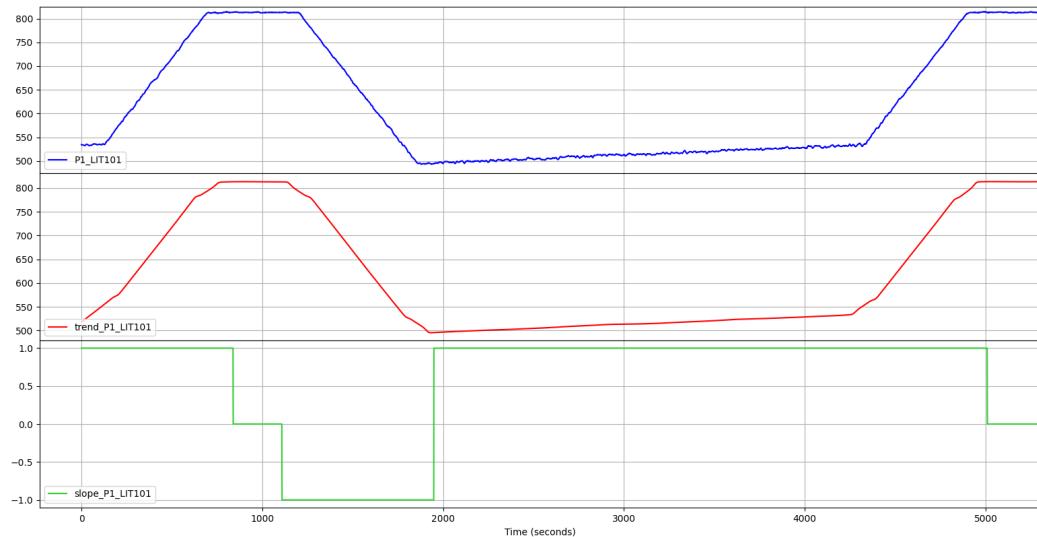

Figure 4.6: The new slope representation (green line) and the smoothed measurement data obtained with the STL decomposition (red)

1894 tional attributes but excludes the timestamp column. This dataset is in-
 1895 tended for inference and invariant analysis. The second dataset does *not*
 1896 contain any additional data and is specifically used in the process mining
 1897 phase. This dataset contains the timestamp.

1898 By default, the enriched dataset will be saved in CSV format in the
 1899 `$(project-dir)/daikon/Daikon_Invariants` directory. The other dataset,
 1900 without additional data, will be saved in the `$(project-dir)/process-mining/data`
 1901 directory. It's worth noting that both paths can be configured in the
 1902 `config.ini` file. The dataset name can be specified in the `config.ini` file or
 1903 through the `-o` command-line option. When generating the dataset for
 1904 process mining, the script will automatically add a `_TS` suffix to the file-
 1905 name to indicate that it includes the timestamp. This flexibility allows the
 1906 user to provide a different filename for each output, preventing overwrit-
 1907 ing of previous datasets. It enables the user to save the execution trace of
 1908 the selected subsystem separately and utilize them in subsequent analysis
 1909 phases.

1910 4.2.3.4 Preliminary Analysis of the Obtained Subsystem

1911 After merging the datasets, the user has the option to perform an **optional analysis** of the resulting dataset to extract preliminary data. This
1912 analysis aims to gather basic information about the (sub)system and po-
1913 tentially refine the enrichment process. If the user chooses to proceed with
1914 the analysis, the `mergeDatasets.py` script invokes another Python script lo-
1915 cated in the `$(project-dir)/pre-processing` directory called `system_info.py`.
1916 Relying on an analysis based on a combination of Daikon and Pandas this
1917 script performs a quick analysis of the dataset allowing to **estimate**, al-
1918beit approximately, the **type of registers** (sensors, actuators, ...), also iden-
1919tifying possible maximum and minimum values of measurements and
1920 hardcoded setpoints. Furthermore, leveraging the use of the additional
1921 attribute `prev_`, the `system_info.py` script is capable of deriving measure-
1922ment values corresponding to state changes of individual actuators. This
1923 allows for the identification of specific measurements associated with the
1924activation or deactivation of certain actuators within the system.
1925 As the last information we have duration of actuator states for each cy-
1926cle of the system: this information can be useful for making assumptions
1927and conjectures about the behavior of an actuator in a specific state or, by
1928observing the duration values of each cycle, highlighting anomalies in the
1929system.

1931

1932 Listing 4.4 shows an example of the output this brief analysis related to
1933 our testbed (for brevity, only one measurement is reported in the analysis
1934 of actuator state changes):

Listing 4.4: Example of preliminary system analysis

The information obtained here can be used, as mentioned above, to refine the enrichment of the dataset by setting directives in the [DATASET] section of the *config.ini* file, should this be empty or only partially set, or to make the first conjectures about the system, as we have just seen.

The *system_info.py* file can also run in standalone mode if needed: it takes as command-line arguments the dataset to be analyzed, a list of actuators, and a list of sensors. For analysis related to state changes, the dataset must mandatorily be of the enriched type.

2013 4.2.4 Phase 2: Graphs and Statistical Analysis

2014 The introduction of the new *graph analysis* is motivavted by from the re-
 2015 quirement to provide users with a comprehensive overview of the (sub)system
 2016 derived from the preceding pre-processing phase. The objective is to facil-
 2017 itate the identification of register types, enhance the understanding of re-
 2018 lationships, and effectively grasp the dynamics among registers controlled
 2019 by one or more PLCs. This analysis component serves to validate initial
 2020 conjectures made during the preliminary analysis described in the previ-
 2021 ous section or generate new insights with the aid of visual chart represen-
 2022 tations. It enables users to gain a deeper understanding of the system by
 2023 leveraging the support of visual charts.

2024 In Ceccato et al.'s framework, as mentioned in Section 3.2.7, it was only
 2025 possible to view the chart of one register at a time. While this allowed for
 2026 the identification or hypothesis of the register type, it made it challenging
 2027 to establish relationships with other components of the system and derive
 2028 conjectures about their behavior. To address this limitation, there was a
 2029 need for a new tool that could provide more information in a more acces-
 2030 sible manner.

2031 Initially, we considered adopting an approach similar to Figure 3.5,
 2032 where all the graphs are displayed within a single plot. However, we soon
 2033 realized that this solution was not feasible and could not be adopted. Fig-
 2034 ure 4.7 helps to understand why.

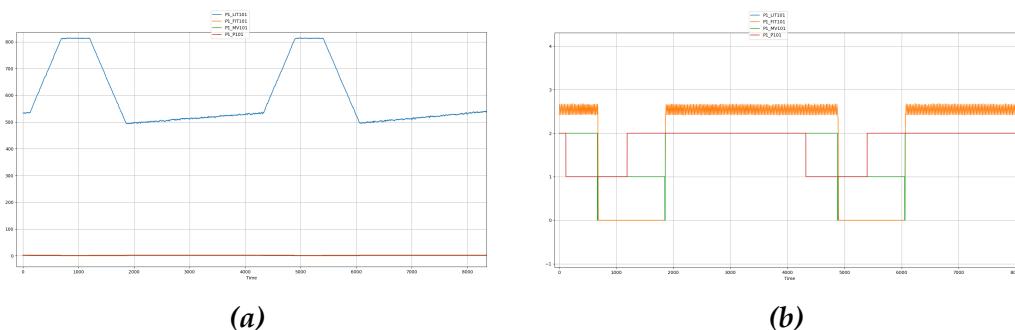

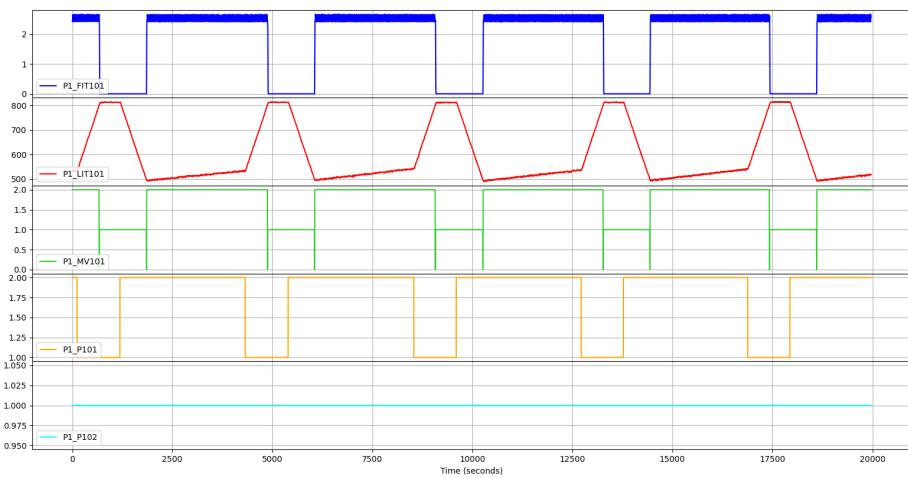

Figure 4.7: Plotting registers on the same y-axis

Figure 4.7a highlights the main issue with this approach, which is the use of the same y-axis for all the charts, representing the values of individual registers. When the range between register values is wide, it can result in some charts appearing as a single flat line or becoming indistinguishable, making them difficult to read. Additionally, as shown in Figure 4.7b, when registers have similar values, the graphs can become confusing and harder to interpret.

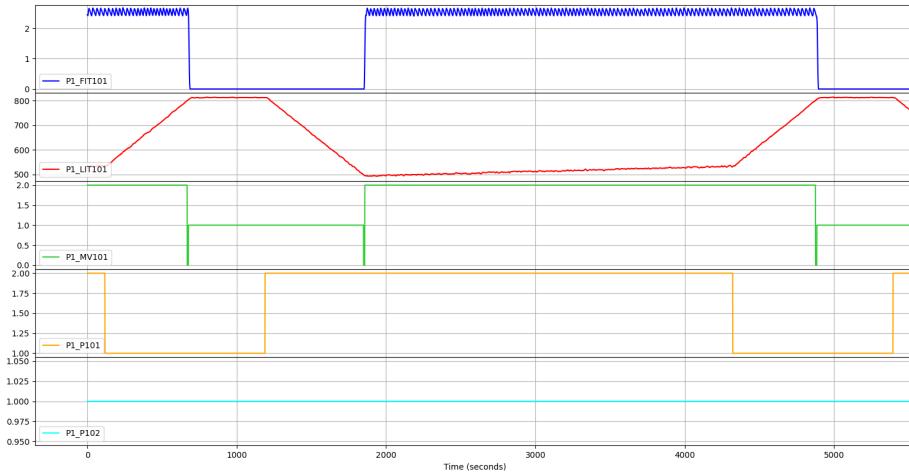

The solution to this issue is simple and effective: the use of **subplots**. Basically, each register corresponds to a subplot of the graph that shares the time axis (the x-axis) with the other subplots, but keeps the y-axis of the values of each register independent. This maintains the readability and comprehensibility of the charts, while simultaneously being able to immediately grasp the relationships between them. In addition, by sharing the time axis, it is possible to zoom in on a particular area of one of the charts and automatically the other ones will be zoomed in as well, thus not losing any information and no connection between registers.

Figure 4.8 illustrates more clearly what has just been explained.

(a) Example of plotting charts of a PLC registers using subplots

Figure 4.8: Example of the new graph analysis

(b) Zooming on a particular zone of the charts

Figure 4.8: Example of the new graph analysis (cont.)

2052 As the reader has probably already noticed, the majority of the graphs
 2053 presented in the previous sections and chapters were generated using the
 2054 new graph analysis script, specifically the `runChartsSubPlots.py` script.
 2055 This Python script is located in the `$(project-dir)/statistical-graphs`
 2056 directory and utilizes the `matplotlib` libraries to generate the graph plots,
 2057 similar to the Ceccato et al.'s tool.

2058 The script accepts the following command-line parameters:

- 2059 • **-f or --filename:** specifies the CVS format dataset to read data from.
 The dataset must be within the directory containing the enriched
 datasets for the invariant analysis phase. If subsequent parameters
 are not specified, the script will display all registers in the dataset,
 excluding any additional attributes;
- 2060 • **-r or --registers:** specifies one or more specific registers to be dis-
 played;
- 2061 • **-a or --addregisters:** adds one or more registers to the default visual-
 ization. This option is useful in case an additional attribute such as
 slope is to be analyzed;

2069 • **-e or --excluderegisters:** excludes one or more specific registers from
2070 the default visualization. This option is useful to avoid displaying
2071 hardcoded setpoints or spare registers.

2072 This script, like the previous ones, is designed to provide the maximum
2073 flexibility and ease of use for the user, combined with greater power and
2074 effectiveness in deriving useful information about the analyzed system.

2075 **Statistical Analysis** After careful consideration, we made the decision
2076 not to include the statistical analysis aspect of the Ceccato et al.'s tool in
2077 the framework. We found that there was no practical use for it. Instead, we
2078 integrated the relevant statistical information into the preliminary analysis
2079 conducted after the pre-processing phase. Additionally, we deemed the
2080 histogram to have limited utility and considered it outdated in comparison
2081 to the new graph analysis approach we implemented.

2082 Although we decided not to include the statistical analysis aspect in the
2083 framework, the Python script `histPlots_Stats.py` from the original tool
2084 remains in the directory. This script is essentially unchanged from the
2085 version developed by Ceccato et al. and can be used in the future if the
2086 need arises.

2087 4.2.5 Phase 3: Invariant Inference and Analysis

2088 The phase of invariant inference and analysis has undergone a redesign
2089 and improvement to offer the user a more comprehensive and easier ap-
2090 proach to identify invariants. This has been achieved through the applica-
2091 tion of new criteria to analyze and reorganize the Daikon analysis results.
2092 The outcome of this is a more compact presentation of information that
2093 highlights the possible relationships among invariants.

2094 The new design not only enables the identification of undiscovered aspects
2095 of the system behavior but also confirms the hypotheses made during the
2096 earlier stages of analysis. This step is now semi-automated, unlike before,
2097 and allows for the analysis of invariants on individual actuator states and
2098 their combinations.

2099 **4.2.5.1 Revised Daikon Output**

2100 To streamline the process of identifying invariants quickly and effi-
2101 ciently, it is necessary to revise the output generated by standard Daikon
2102 analysis. The goal is to create a more compact and readable format for the
2103 output.

2104 The current Daikon results basically consist of three sections, referred
2105 as *program point sections* [64]:

- 2106 1. the first section containing **general invariants**, i.e., valid regardless
2107 of whether a condition is specified for the analysis;
- 2108 2. the second section containing **conditional invariants**, obtained by
2109 specifying conditions for the analysis in the *.spininfo* file.
- 2110 3. a third section containing the invariants that are obtained from the
2111 **negation of the condition** potentially specified in the *.spininfo* file.

2112 In each section only a single invariant per row is shown, without relat-
2113 ing it in any way to the others: this makes it difficult to identify significant
2114 invariants and any invariant chain that might provide much more infor-
2115 mation about the behavior of the system than the single invariant.

2116 A brief example of the structure and format of this output related to
2117 PLC1 of the iTrust SWaT system is shown in Listing 4.5, where a condition
2118 was specified on the measurement LIT101 and on actuator MV101:

```
2119    aprogram.point:::POINT
2120     P102 == prev_P102
2121     FIT101 >= 0.0
2122     MV101 one of { 0.0, 1.0, 2.0 }
2123     P101 one of { 1.0, 2.0 }
2124     P102 == 1.0
2125     max_LIT101 == 816.0
2126     min_LIT101 == 489.0
2127     slope_LIT101 one of { -1.0, 0.0, 1.0 }
2128     [...]
2129     LIT101 > MV101
```

```

2130      LIT101 > P101
2131      LIT101 > P102
2132      LIT101 < max_LIT101
2133      LIT101 > min_LIT101
2134      [...]
2135      MV101 < min_LIT101
2136      MV101 < trend_LIT101
2137      P101 >= P102
2138      P101 < max_LIT101
2139      [...]
2140      =====
2141     aprogram.point:::POINT;condition="MV101 == 2.0 && LIT101 <
2142      ↪ max_LIT101 - 16 && LIT101 > min_LIT101 + 15"
2143      MV101 == prev_MV101
2144      P102 == slope_LIT101
2145      MV101 == 2.0
2146      FIT101 > MV101
2147      FIT101 > P101
2148      FIT101 > P102
2149      FIT101 > prev_P101
2150      MV101 >= P101
2151      MV101 >= prev_P101
2152      P101 <= prev_P101
2153      =====
2154      aprogram.point:::POINT;condition="not(MV101 == 2.0 &&
2155      ↪ LIT101 < max_LIT101 - 16 && LIT101 > min_LIT101 + 15)
2156      ↪ "
2157      P101 >= prev_P101
2158      Exiting Daikon.

```

Listing 4.5: Standard Daikon output for PLC1 of the iTrust SWaT system

2159 In the presented framework, the output is simplified to **two sections**:
2160 the *general section* and the section related to the *user-specified condition*. The
2161 section related to the negated condition is eliminated as it is not relevant in
2162 this context and could lead to potential misinterpretation. Moreover, the
2163 relationships between invariants will be emphasized by utilizing **transitive closures**:
2164 transitive closure of a relation R is another relation, typically
2165 denoted R^+ that adds to R all those elements that, while not necessarily

related directly to each other, can be reached by a *chain* of elements related to each other. In other words, the transitive closure of R is the smallest (in set theory sense) transitive relation R such that $R \subset R^+$ [65].

To implement the transitive closure of the invariants generated by Daikon, we initially categorized the invariants in each section by type based on their mathematical relation ($==$, $>$, $<$, \geq , \leq , $!=$), excluding any invariant related to additional attributes except for the slope. For each type of invariant, we constructed a **graph** using the NetworkX library, where registers were represented as nodes, and arcs were created to connect registers that shared a common endpoint in the invariant, applying the transitive property. To reconstruct the individual invariant chains, we employed a straightforward approach known as *Depth-first Search* (DFS) on each of the graphs. This method allowed us to traverse the graphs and obtain the desired outcome, identifying the invariant chains. Figure 4.9 shows some examples of these graphs:

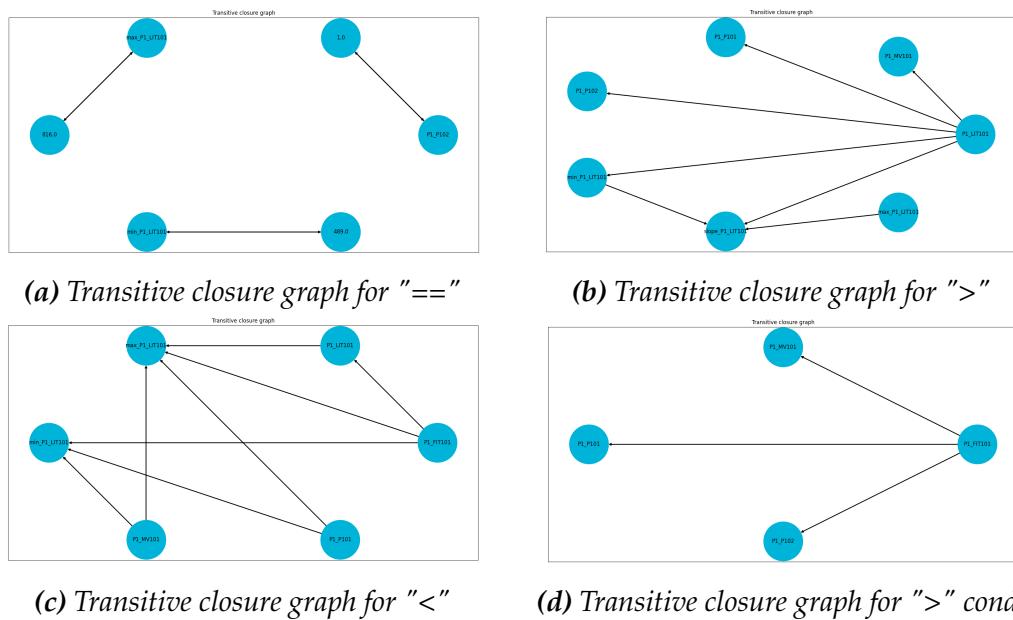

Figure 4.9: Example of transitive closure graphs for invariants in PLC1 of iTrust SWaT system

At the end of this process, still applied to PLC1 of the iTrust SWaT sys-

2182 tem and with the same analysis condition, we get the following complete
 2183 output:

```

2184 1 =====
2185 2 General
2186 3 =====
2187 4 MV101 one of { 0.0, 1.0, 2.0 }
2188 5 P101 one of { 1.0, 2.0 }

```

***Listing 4.6:** Revised Daikon output with transitive closures for PLC1 of the iTrust SWaT system*

2211 Transitive closures can be appreciated in lines 7, 14 and 16 of Listing 4.6.
 2212 In general, the output has been reduced in the number of effective rows
 2213 (19 versus the 61 in the output of Listing 4.5, making it certainly better to
 2214 read and identify significant invariants) and the invariant chains make it
 2215 more immediate to grasp the relationships between registers.

2216 **4.2.5.2 Types of Analysis**

2217 In contrast to Ceccato et al.'s solution, which involves manual individual analyses, our proposal is to introduce **two types of semi-automated analysis**.

2220 The first type focuses on analyzing **all states for each individual actuator**.
2221 This automated analysis aims to provide comprehensive insights into the behavior of each actuator in relation to a specific measurement selected by the user.

2224 The second type of analysis considers the current system configuration
2225 and examines the **actual states of the actuators**. This analysis takes into account the interplay and combined effects of multiple actuators on the selected measurement. By incorporating the real-time states of the actuators, this semi-automated analysis offers a more accurate assessment of the system behavior.

2230 These two types of analysis will be handled by the Python script
2231 `daikonAnalysis.py`, contained in the default directory `$(project_dir)/daikon`.
2232 The script accepts the following command-line arguments:

- 2233 • **-f or --filename**: specifies the enriched dataset, in CSV format, from
2234 which to read the data. The dataset must be located within the directory containing the enriched datasets specified in the `config.ini` file
2235 (by default `$(project_dir)/daikon/Daikon_Invariants`);
- 2237 • **-s or --simpleanalysis**: performs the analysis on the states of individual actuators;
- 2239 • **-c or --customanalysis**: performs the analysis on combinations of actual states of the actuators;
- 2241 • **-u or --uppermargin**: defines a percentage margin on the maximum value of the measurement;
- 2243 • **-l or --lowermargin**: defines a percentage margin on the minimum value of the measurement;

2245 The selection of one or both types of analysis is possible. Additionally,
2246 the last two parameters can be used to set a condition on the value of the
2247 measurement. This condition is designed to bypass the transient periods
2248 that occur during actuator state changes and the actual trend changes at
2249 the maximum and minimum values of the measurement.
2250 This approach proves particularly beneficial for the first type of analysis,
2251 as it enables more accurate data on the trends of the measurement. By
2252 excluding the transient periods, the analysis can focus on the stable and
2253 meaningful trends, providing improved insights into the behavior of the
2254 system.

2255 **Analysis on single actuator states** Analysis on the states of individual
2256 actuators is the simplest: after the user is prompted to input the measure-
2257 ment, chosen from a list of likely available measurements, the script rec-
2258ognizes the likely actuators and the relative states of each, using the same
2259 mixed Daikon/Pandas technique adopted in the preliminary analysis dur-
2260 ing the pre-processing phase.
2261 For each actuator and each state it assumes, a single Daikon analysis is
2262 performed, eventually placing the condition on the maximum and mini-
2263 mum level of the measurement.
2264 The result of these analyses are saved in the form of text files in a directory
2265 having the name corresponding to the analyzed actuator and contained in
2266 the default parent directory `$(project_dir)/daikon/Daikon_Invariants/results`:
2267 each file generated by the analysis is identified by the name of the actuator,
2268 the state and the condition, if any, on the measurement (see Figure 4.10).

2269 Listing 4.6 provides an illustrative example of the analysis results. In
2270 this case, we focus on the actuator MV101 in state 2.

2271 The condition-generated invariants provide the most interesting insights.
2272 For example, at line 21, we observe that when MV101 is set to 2, the slope of
2273 LIT101 is 1, indicating an increasing trend. This leads us to speculate that
2274 MV101 represents the actuator's ON state and is responsible for filling the
2275 tank (LIT101).

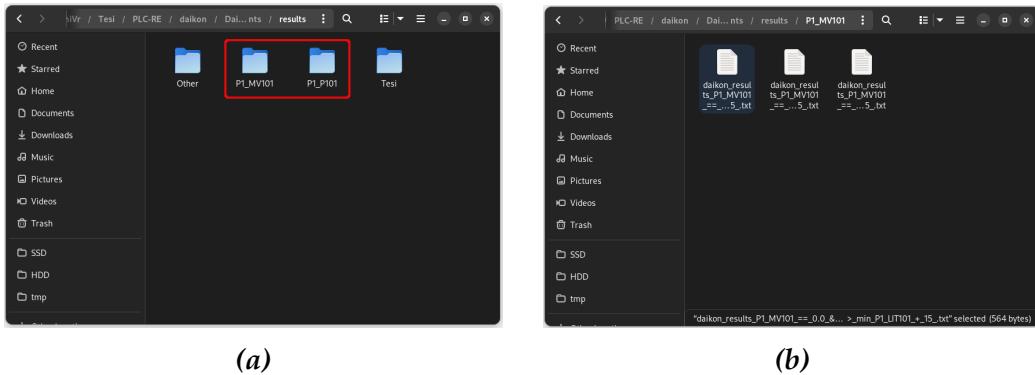

Figure 4.10: Directory (a) and outcome files (b) for the single actuator states analysis

2276 Analysis of the Current System Configuration The analysis of the cur-
2277 rent system configuration based on the actual states of the actuators is
2278 more complex, but at the same time offers more interesting outcomes as
2279 it provides better evidence of actuator behavior in relation to the selected
2280 measurement.

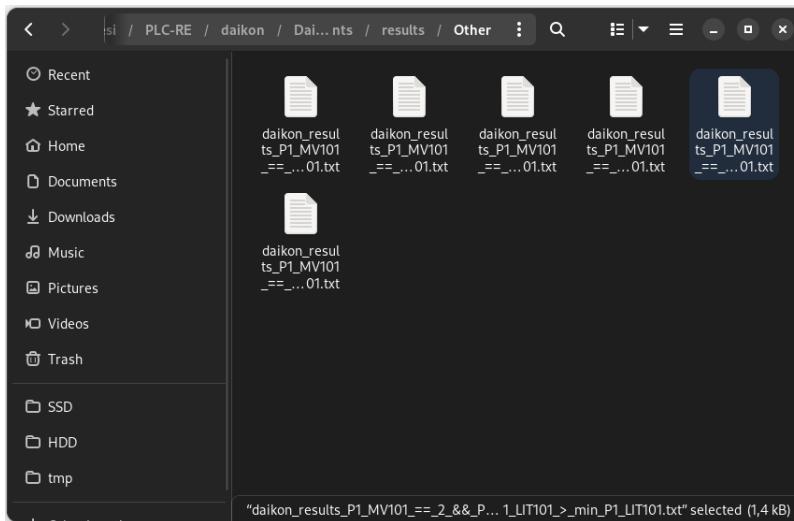

Figure 4.11: Daikon outcome files for system configuration analysis. Each file represents a single system state

For this analysis, the script automatically identifies the configurations of the actuators that represent different system states (e.g., $MV101 == 2$, $P101 == 1$). Daikon analysis is then performed for each of these configurations.

2284 The user is prompted to select the measurement attribute and, if desired,
 2285 specific actuators for studying their configurations. If no actuators are se-
 2286 lected, all previously detected actuators will be considered.

2287 The analysis results are saved in text format within a designated directory,
 2288 located alongside the previous analysis outputs. The filenames of these
 2289 result files follow a specific naming convention based on the analysis rule
 2290 applied (see Figure 4.11).

2291

2292 An example of the obtained outcomes can be seen in Listing 4.7:

```

2293 1 =====
2294 2 General
2295 3 =====
2296 4 MV101 <= P101 ==> FIT101 >= 0.0
2297 5 MV101 <= P101 ==> MV101 one of { 0.0, 1.0, 2.0 }
2298 6 MV101 <= P101 ==> P101 one of { 1.0, 2.0 }
2299 7 MV101 <= P101 ==> slope_LIT101 one of { -1.0, 0.0, 1.0 }
2300 8 MV101 > P101 ==> FIT101 > MV101
2301 9 MV101 > P101 ==> FIT101 > P101
2302 10 MV101 > P101 ==> FIT101 > P102
2303 11 MV101 > P101 ==> FIT101 > slope_LIT101
2304 12 MV101 > P101 ==> MV101 == 2.0
2305 13 MV101 > P101 ==> MV101 > P102
2306 14 MV101 > P101 ==> MV101 > slope_LIT101
2307 15 MV101 > P101 ==> P101 == 1.0
2308 16 MV101 > P101 ==> P101 == P102
2309 17 MV101 > P101 ==> P101 == slope_LIT101
2310 18 MV101 > P101 ==> slope_LIT101 == 1.0
2311 19 [...]
2312 20
2313 21 =====
2314 22 MV101 == 2 && P101 == 1 && LIT101 < max_LIT101 && LIT101 >
2315 23 ↢ min_LIT101
2316 24 =====
2317 25 slope_LIT101 == P102 == P101 == 1.0
2318 26 MV101 == 2.0
2319 27 FIT101 > MV101

```

2320 27 FIT101 > P101

Listing 4.7: Daikon outcomes for the system configuration MV101 == 2, P101 == 1 on LIT101

2321 In contrast to Listing 4.6, the current analysis reveals the presence of impli-
2322 cations in the general invariants section, which were previously absent (re-
2323 maining generic invariants omitted for brevity). These implications offer
2324 valuable insights, as demonstrated in this case. For instance, the invariant
2325 stated in line 18 informs us that if the value of MV101 is greater than P101,
2326 then the slope's value is 1, indicating an increasing tank level. This finding
2327 further corroborates our previous understanding that the state MV101 ==
2328 2 represents the ON state for the actuator responsible for filling the tank,
2329 namely LIT101.

2330 **Refining the Analysis** In certain situations, the outcomes provided by
2331 the semi-automated analyses may not meet the user's expectations. For
2332 instance, the clarity of the slope value may be insufficient, or the user may
2333 wish to delve deeper into a specific aspect of the system to uncover ad-
2334 ditional invariants that were not previously identified. In such cases, the
2335 user has the option to conduct a more targeted and specific invariant anal-
2336 ysis using the Python script `runDaikon.py`, which enables precise investi-
2337 gations of the system.

2338 The script, located in the default directory `$(project_dir)/daikon`, can be
2339 executed with three command-line parameters:

- 2340 • **-f or --filename:** specifies the CSV format *enriched* dataset to read
2341 data from. Even in this case, the dataset must be located within the
2342 directory containing the enriched datasets;
- 2343 • **-c or --condition:** specifies the condition for the analysis, which will
2344 be automatically overwritten in the `.spinfo` file. It is possible to spec-
2345 ify more than one condition, but it is strongly recommended to use
2346 the logical operator `&&` to avoid undesired behaviors in Daikon out-
2347 comes;

- 2348 • **-r or --register:** specifies the directory where to save the text file with
2349 the outcomes.

2350 During the execution of this analysis, a single output file is generated, con-
2351 taining the discovered invariants. The user can specify the directory where
2352 this file should be saved using the **-r** command-line option. By default, the
2353 file is stored in the directory `$(project_dir)/daikon/Daikon_Invariants/results`.
2354 The output file serves as a record of the identified invariants and can be
2355 examined at a later time.

2356 In conclusion, the integration of these two analysis types, along with
2357 the ability to conduct more refined analysis in the future and the enhanced
2358 output format of Daikon, significantly enhances the completeness, clarity,
2359 and effectiveness of this stage compared to the Ceccato et al.'s framework.

2360 4.2.6 Phase 4: Business Process Analysis

2361 We have made significant revisions to the Business Process Analysis
2362 we are presenting. Instead of relying on the previous Java solution and
2363 proprietary process mining software Disco, we have adopted a **new inte-**
2364 **grated solution** created in Python from scratch. The new solution utilizes
2365 the Graphviz libraries to generate the corresponding activity diagram.

2366
2367 In this updated Business Process, greater emphasis is placed on process
2368 mining related to the physical system. Our goal is to extract as much
2369 information as possible from the dataset, enabling us to promptly visu-
2370 alize the system's behavior and its various states. This approach allows
2371 us to validate the conjectures and hypotheses formulated in the previ-
2372 ous phases, and potentially uncover hidden patterns that were previously
2373 undisclosed.

2374 On the other hand, the aspect related to network communications was
2375 reconsidered to enable operation with multiple protocols, expanding be-
2376 yond the limitations of Modbus.

2377

2378 Now, let's examine the key aspects of this new phase in greater detail.

2379 **4.2.6.1 Process Mining of the Physical Process**

2380 The mining of the physical process is performed by the Python script
2381 called `processMining.py`, located in the default directory `$(project_dir)/process-mining`.
2382 This script accepts the following parameters from the command line:

- 2383 • **-f or --filename:** specifies the CSV format *timestamped* dataset to be
2384 mined from. The dataset is obtained from the pre-processing stage
2385 and is located in the default directory `$(project_dir)/process-mining/data`;
- 2386 • **-a or --actuators:** specifies one ore more actuators whose combina-
2387 tions of states are to be analyzed. If this parameter is not provided,
2388 all actuators in the subsystem will be considered;
- 2389 • **-s or --sensors:** specifies one or more measurements for which the
2390 trend will be calculated based on actuator state changes. If this pa-
2391 rameter is omitted, all available measurements will be considered;
- 2392 • **-t or --tolerance:** specifies the tolerance to be taken into account dur-
2393 ing the trend calculation;
- 2394 • **-g or --graph:** shows the resulting activity diagram.

2395 The script processes the dataset in a sequential manner, analyzing each
2396 actuator state change. It calculates the duration in seconds of the system
2397 state, as well as the trend and slope of the specified measurement(s). Addi-
2398 tionally, the script stores the next system state and the measurement values
2399 corresponding to the state change points, allowing for the identification of
2400 relative setpoints. These results are gradually collected and stored in a dic-
2401 tionary, where the keys represent the system states based on the actuator
2402 configurations, and the values represent the measured values mentioned
2403 above. The dictionary is then saved as a JSON file, which can be accessed
2404 by the user in the `$(project_dir)/process-mining/data` directory. The

2405 name of the file can be specified in the configuration file *config.ini*.

2406

2407 An example of the JSON file obtained in this step is shown in Listing 4.8:
2408 the JSON file showcases the structure of the data obtained during the pro-
2409 cess.

```
2410 {
2411     "MV101 == 2, P101 == 2": {
2412         "start_value_LIT101": [

2459   ...
2460 }
2461 ...
2462 ...
2463 }
```

Listing 4.8: Example of the data contained in the produced JSON file

The collected data is now utilized to generate the **system activity diagram**. This diagram represents an *oriented* graph where the nodes correspond to the system states determined by the actuator configurations. In addition to the state information, the nodes also display the trend (ascending, descending, or stable) and the slope of the reference measurement. The edges in the diagram depict the values of the measurements at the time of the state change. These measurement values represent the setpoints for each measurement. Setpoints are calculated on the average of the values measured for that specific state. Additionally, the diagram incorporates on the edges the average duration of each system state. Each data point on the arcs is accompanied by a *standard deviation value*. This value provides information about the occurrence of a specific state within the system's cycle, indicating whether it appears multiple times with varying values and time durations. A low standard deviation sug-

2478 gests that the state is likely to occur only once within each cycle. Con-
 2479 versely, a high standard deviation indicates that the state may occur mul-
 2480 tiple times within the cycle.

2481 An example of the activity diagram generated by the processMining.py
 2482 script is presented in Figure 4.12. This diagram illustrates the system's
 2483 behavior by depicting transitions between different states. Nodes in the
 2484 diagram represent specific system states, while arrows or edges indicate
 2485 the flow between these states.

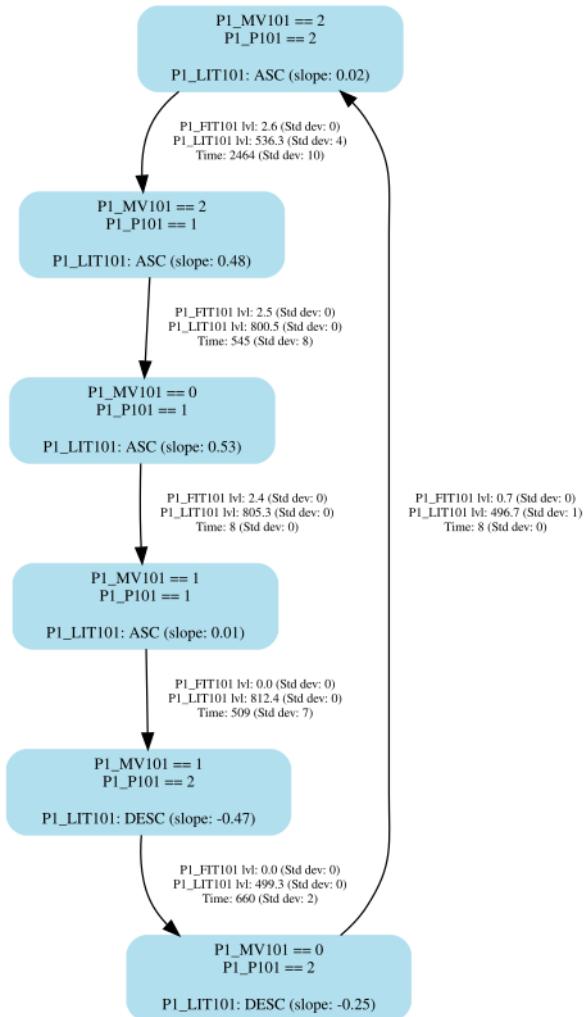

Figure 4.12: Activity diagram for PLC1 of the iTrust SWaT system

2486 The diagram reveals important aspects of the system, such as its **periodicity**
2487 and the emphasis on the **temporal sequence of actuator states**. These
2488 insights might not have been clearly evident in earlier stages of the anal-
2489 ysis. The diagram provides a visual representation that allows us to ap-
2490 preciate the recurring patterns and understand how the system evolves
2491 over time. By observing the transitions and relationships between differ-
2492 ent states, we gain a better understanding of the dynamics and behavior
2493 of the system.

2494 It is important to acknowledge that despite considering the tolerance
2495 set for trend and slope calculation, the accuracy of the related data may
2496 vary. For instance, there could be instances where multiple trends exist
2497 within the same node, or a trend may be stable instead of increasing or de-
2498 creasing. These discrepancies arise due to **data perturbations**, which were
2499 discussed in Section 4.2.3.2. Additionally, the noise reduction techniques
2500 seen in the same Section were not employed in this analysis. Therefore, it
2501 becomes the responsibility of the user to correctly interpret the outcomes
2502 of this step, taking into account the information presented in the process
2503 mining diagram and the findings from previous analyses. By consider-
2504 ing these factors together, the user can make informed interpretations and
2505 draw accurate conclusions from the results.

2506 4.2.6.2 Network Communications

2507 The incorporation of network communications into Business Process
2508 Analysis has been reconsidered to shift away from a *single-protocol* solu-
2509 tion based on Modbus. Instead, the focus is on adopting a solution that
2510 can handle **multiple protocols**, even at the same time.
2511 The main concept was to develop a new Python script that would extract
2512 and process data from PCAP files obtained through network traffic sniff-
2513 ing. The intention was to export this data to a CSV file, which would then
2514 be used as input for the process mining script, `processMining.py`, and inte-
2515 grated with the physical system data to derive commands to the actuators.

2516 The analysis of the network data revealed that different protocols ex-
2517 hibit distinct behaviors when commanding changes in actuator states. Con-
2518 sequently, the previous approach proposed by Ceccato et al. becomes **im-**
2519 **practical** when attempting to detect system state changes through network
2520 commands sent to the actuators.

2521 However, considering that system state changes have already been iden-
2522 tified through the process mining of the physical process, and with the
2523 corresponding event timestamps available, we propose an alternative ap-
2524 proach to Ceccato et al.'s method. Instead of seeking the correspondence
2525 between network events and physical process events at the same instant,
2526 we suggest reversing the perspective. By focusing on the correspondence
2527 between a given event occurring in the physical process at a specific mo-
2528 ment and the corresponding event in the network data at the same mo-
2529 ment, it should be possible to achieve a similar, if not superior, outcome
2530 compared to the previous solution.

2531

Case study: the iTrust SWaT System

2532 HAVING introduced the innovative framework and highlighted its po-
2533 tential in the preceding chapter, we now turn our attention to the
2534 case study where we will apply this framework. As previously mentioned
2535 in Chapter 4 and demonstrated through various examples in the same
2536 chapter, our focus will be on the **iTrust SWaT system** [36], developed by
2537 the iTrust – Center for Research in Cyber Security of University of Singa-
2538 pore for Technology and Design [30]. The acronym SWaT represents *Secure*
2539 *Water Treatment*.

2540 The iTrust SWaT system is a testbed that replicates on a small scale
2541 a real water treatment plant arises to support research in the area of cy-
2542 ber security of industrial control systems and has been operational since
2543 March 2015: it is still being used by students at the University of Singapore
2544 for educational and training purposes and is available to organizations to
2545 train their operators on cyber physical incidents.

2546 5.1 Architecture

2547 In contrast to the virtualized testbed discussed in Section 3.2.1 by Cec-
2548 cato et al., the iTrust SWaT system is composed entirely of physical hard-
2549 ware components. It encompasses various elements, starting from field

2550 devices and extending to PLCs, HMI, SCADA workstations, and the SCADA
2551 server (also referred to as the *historian*). The historian is responsible for
2552 recording data from field devices for further analysis. In the upcoming
2553 sections, we will delve deeper into the architecture of the physical process
2554 and the communication network.

2555 **5.1.1 Physical Process**

2556 The physical process of the SWaT consists of six stages, denoted P1
2557 through P6. These stages are [66][67]:

- 2558 P1. **taking in raw water:** feeds unfiltered water into the system
- 2559 P2. **chemical dosing:** adds chemicals to water useful for initial pretreat-
2560 ment;
- 2561 P3. **Ultra Filtration (UF) system:** the water is filtered through a semi-
2562 permeable membrane (ultrafiltration membrane) using the liquid pres-
2563 sure, effectively capturing impurities and suspended solids, as well
2564 as removing bacteria, viruses, and other pathogens present in the
2565 water;
- 2566 P4. **dechlorination:** removes residual chlorine from disinfected water
2567 using ultraviolet lamps;
- 2568 P5. **Reverse Osmosis (RO):** performs further filtration of the water;
- 2569 P6. **backwash process:** cleans the membranes in UF using the water pro-
2570 duced by RO.

2571 Figure 5.1 shows a graphical representation of the architecture and the six
2572 stages of the SWaT system.

2573 The SWaT system incorporates an array of sensors that play a crucial
2574 role in monitoring the system's operations and ensuring their safe. These
2575 sensors are responsible for continuously collecting data and providing
2576 valuable insights into the functioning of the system. These sensors are:

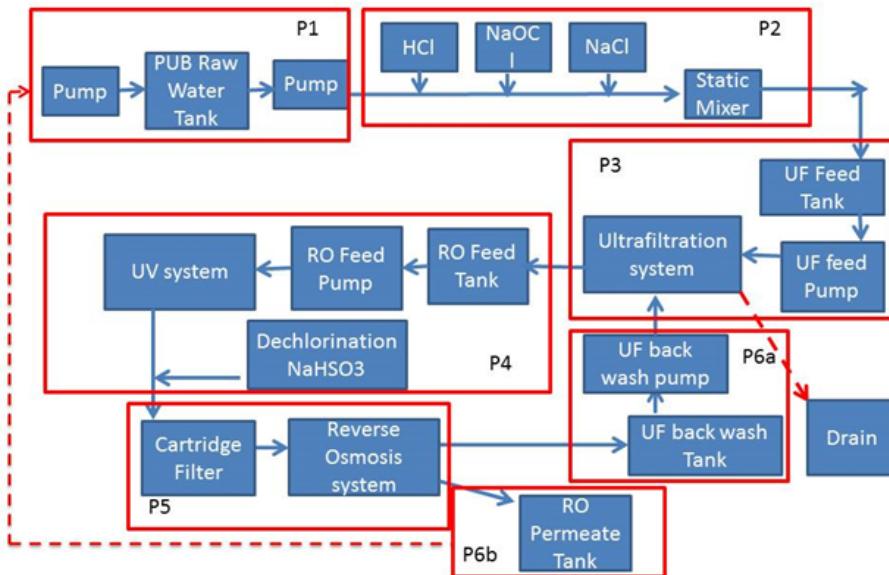

Figure 5.1: SWaT architecture

- Level Indication Transmitter (measured in mm)
- Flow Indication Transmitter (m³/hr)
- Analyser Indicator Transmitter
 - Conductivity ($\mu\text{S}/\text{cm}$)
 - pH
 - Oxidation Reduction Potential (mV)
- Differential Pressure Indicator Transmitter (kPa)
- Pressure Indicator Transmitter (kPa)

The sensors and actuators associated with each PLC are shown in Figure 5.2.

Sensors and actuators are mapped to tags by the communication protocol used (see 5.1.2): a tag can be addressed via string descriptor defined by the system designer (e.g. MV101, to indicate motorized valve number 1 at stage 1) or by referring directly to the analog/digital pins of the PLC I/O unit [67].

| | | | | PIT-503 0.00 kPa | |

Figure 5.2: Sensors and actuators associated with each PLC

5.1.2 Control and Communication Network

The SWaT system's network architecture follows the principles of layering and zoning, which enable segmentation and control of traffic within the network.

- Five layers are present starting from the highest to the lowest:
- Layer 3.5 – Demilitarized Zone (DMZ);
 - Layer 3 – Operation Management (Historian);
 - Layer 2 – Supervisory Control (Touch Panel, Engineering Workstation, HMI Control Clients);
 - Layer 1 – Plant Control Network (PLCs) (Star Network);
 - Layer 0 – Process (Actuator/Sensors and Input/output modules) (Ring Network).

PLCs at Layer 1 communicate with their respective sensors and actuators at Layer 0 through a conventional ring network topology based on EtherNet/IP, to ensure that the system can tolerate the loss of a single link

2608 without any adverse impact on data or control functionality.
 2609 PLCs between the different process stages at Layer 1 communicate with
 2610 each other through a star network topology using the CIP protocol on Eth-
 2611 erNet/IP, previously discussed in Section 2.2.6.3.

2612 Regarding zoning, the SWaT system is divided into three zones, each
 2613 containing one or more layers. These zones are, in descending order of
 2614 security level:

- 2615 • **Plant Control Network, or Control System:** includes layers from 0
 2616 to 2;
- 2617 • **DMZ:** includes Layer 3.5;
- 2618 • **Plant Network:** includes Layer 3;

2619 Figure 5.3 provides a clearer visualization of the zoning and layer division
 2620 within the network architecture of the SWaT system. This diagram high-
 2621 lights the distinct zones and their corresponding layers, offering a com-
 2622 prehensive overview of the system's network structure.

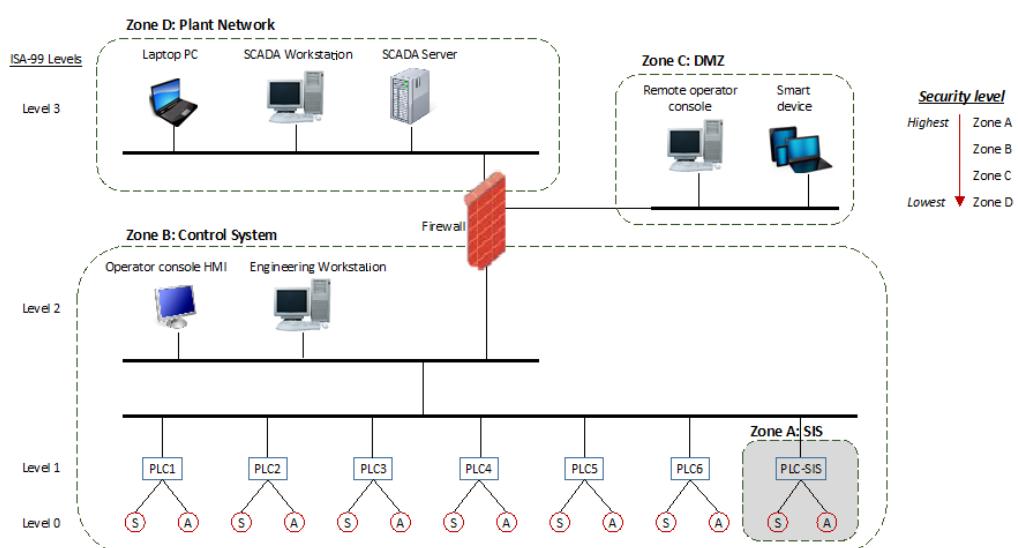

Figure 5.3: SWaT network architecture

2623 A specific IP address is associated with each device: in Table 5.1 we
2624 report the addresses for the PLCs, historian, and Touch Panel in the *Plant*
2625 *Control Network* (PCN) zone:

| IP Address | Device |
|---------------|-------------------------|
| 192.168.1.10 | PLC1 |
| 192.168.1.20 | PLC2 |
| 192.168.1.30 | PLC3 |
| 192.168.1.40 | PLC4 |
| 192.168.1.50 | PLC5 |
| 192.168.1.60 | PLC6 |
| 192.168.1.100 | Touch Panel (PCN) |
| 192.168.1.200 | Historian Server |
| 192.168.1.201 | Engineering Workstation |

Table 5.1: main IP addresses of the six PLCs and SCADA in SWaT

2626 5.2 Datasets

2627 To facilitate the study and testing of technologies related to cyber security
2628 in Industrial Control Systems and critical infrastructure, iTrust offers
2629 researchers worldwide the opportunity to access a range of datasets [68].
2630 These datasets consist of a collection of data obtained from the SWaT sys-
2631 tem, encompassing information on both the physical processes and net-
2632 work communications. The data is organized into different years, and
2633 researchers can request access to these datasets for their analysis and ex-
2634 perimentation purposes.

2635 **Physical Process Datasets** The datasets containing information about
2636 the physical processes are provided in CSV format files. These files en-
2637 compass data collected during different time intervals, which can vary
2638 from a few hours to entire days. The granularity of the data is typically

2639 at a one-second interval, although there may be some exceptions. The col-
2640 lected data primarily consists of timestamped sensor measurements and
2641 actuator status values for each PLC, describing the physical properties of
2642 the testbed in operational mode.

2643 **Network Communications Datasets** Network communications are typi-
2644 cally available in the form of *Packet Capture* format (PCAP) files. These files
2645 contain captures of communication network traffic, allowing researchers
2646 to analyze and examine the network interactions. In some instances, CSV
2647 files are provided instead of PCAP files, featuring different characteristics
2648 for the collected data.

2649 5.2.1 Our Case Study: the 2015 Dataset

2650 The dataset selected as a case study to apply the framework discussed
2651 in the previous chapter is specifically the dataset from the year 2015 [69].
2652 The main reason for this choice is the unique characteristics found in the
2653 physical process dataset that are not present in datasets from subsequent
2654 years.

2655 **Physical Process Data** The data collection process lasted 11 consecutive
2656 days, 24 hours per day. During the first 7 days, the system operated nor-
2657 mally without any recorded attacks. However, attacks were observed dur-
2658 ing the remaining 4 days. The collected data reflects the impact of these
2659 attacks, leading to the creation of two separate CSV files: one containing
2660 the recorded data of SWaT during the system's regular operations, and
2661 the other containing data recorded during the days of the attacks. To en-
2662 sure accurate information about the system, the dataset pertaining to the
2663 normal operations, which spans seven days, was chosen for analysis.

2664 Data collection occurs at a frequency of one data point per second,
2665 with the assumption that significant attacks cannot occur within a shorter
2666 time frame. Additionally, the firmware of the PLCs remains unchanged
2667 throughout the data collection period.

At the beginning of data gathering the tanks are empty and the system must be initialized in order to then reach full operation: it typically takes around five hours for all tanks to be fully filled and for the system to stabilize and reach the appropriate operational state (see Figure 5.4).

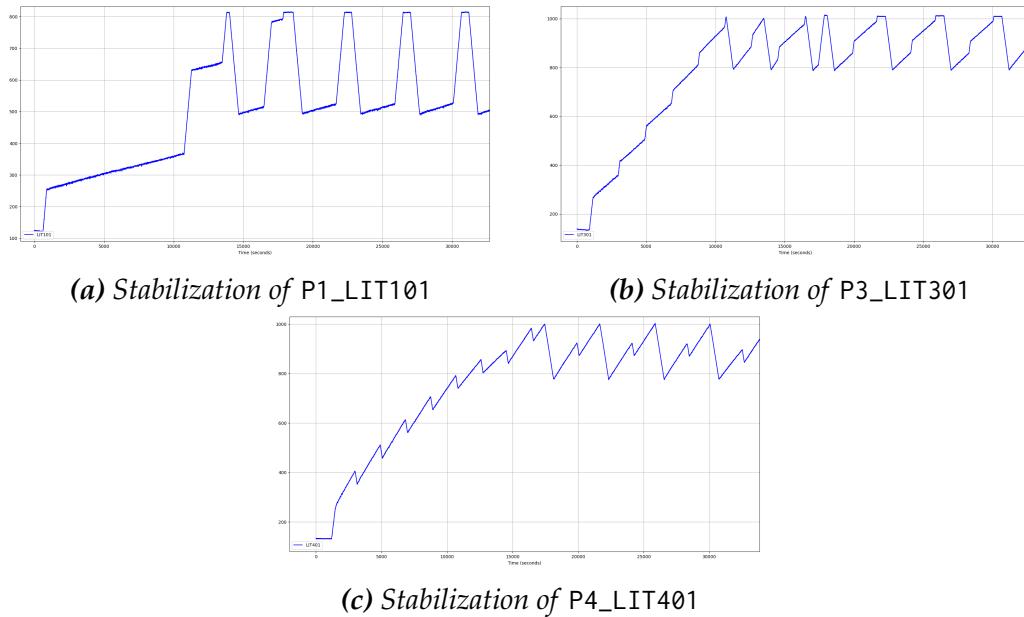

Figure 5.4: SWaT stabilization

In total, the dataset consists of thousand and thousand of samples related to 51 attributes.

2674 **Network Traffic** The network traffic was collected using an appliance
2675 from a well-known network hardware manufacturer and was made avail-
2676 able only in CSV format and not PCAP format. Table 5.2 shows some of
2677 the main data captured:

| Category | Description |
|-----------|----------------------|
| Date | Date of Log |
| Time | Time of Log |
| Origin | IP of server |
| Source IP | IP address of source |

| | |
|-----------------------------|-------------------------------|
| Destination IP | IP address of destination |
| Protocol | Network protocol |
| Application Name | Name of application |
| Modbus Function Code | Function Code |
| Modbus Function Description | Description of function |
| Modbus Transaction ID | Transaction ID |
| SCADA Tag | Sensor or actuator ID |
| Modbus Value | Value transmitted |
| Service / Destination Port | Port number of destination IP |
| Source Port | Port number of source IP |

Table 5.2: SWaT network traffic data

2678 Unfortunately, the data provided are partial as it only includes read-
 2679 ings from sensors and does not include information on actuator status.

2680

2681 Do not mislead by the word *Modbus* in the captured data fields: this is
 2682 most likely a feature of the sniffing appliance, which may have encapsu-
 2683 lated EtherNet/IP-CIP protocol packets in Modbus frames, as described
 2684 by T. A. Snide in [70].

2685 To provide evidence that the protocol being used is CIP over EtherNet/IP,
 2686 we can examine the "Source / Destination port" field in the captured data.

2687 The presence of TCP port 44818 as the destination port aligns with the
 2688 TCP port used for transporting **explicit messages** in the EtherNet/IP pro-
 2689 tocol, as explained in Section 2.2.6.2. Additionally, the "Application name",
 2690 "Modbus Function Code" and "Modbus Function Description" fields fur-
 2691 ther support this conclusion. The "Application name" explicitly states
 2692 "CIP_read_tag_service," while the "Modbus Function Code" field contains
 2693 a decimal value of 76, which does not correspond to any known Modbus
 2694 Function Calls. When converted to hexadecimal, this value is 4C, match-
 2695 ing the CIP protocol read tag request code as indicated in the "Modbus
 2696 Function Description" field.

2697 In summary, the datasets for subsequent years were not selected due

2698 to certain limitations. In the case of the year 2017, the physical system
2699 data had a wide granularity, resulting in significant information loss. Ad-
2700 ditionally, in some cases, the datasets were considered "spurious" as there
2701 was no clear differentiation between data obtained during normal SWaT
2702 operations and data associated with attacks.

2703 Regarding network traffic data, there were instances where the data was
2704 either missing or fragmented into large PCAP files weighing several gi-
2705 gabytes (more than 6 GB each!), despite containing only a few minutes'
2706 worth of data. This made it impractical to manage such files given the
2707 available resources.

2708 Despite their large quantity, the CSV files associated with network traffic
2709 for the year 2015 are comparatively smaller in size, just slightly over 100
2710 MB each. These files cover a more extensive time period, which facilitates
2711 easier management and analysis. Prioritizing the physical process dataset
2712 as crucial, I have selected the year 2015 as a case study, even though the
2713 network data may be incomplete.

Our Framework at Work: Reverse Engineering of the iTrust SWaT System

2714 IN THIS chapter, our main objective is to apply the framework and method-
2715 ology introduced in Chapter 4 to the case study of the iTrust SWaT sys-
2716 tem, as illustrated in Chapter 5. The purpose of this analysis is to assess
2717 the effectiveness and potential of the proposed framework within the con-
2718 text of a system that closely replicates a real-world water treatment plant,
2719 albeit on a smaller scale.

2720 Due to the complexity of the system and the limited space available
2721 in this thesis, we will not conduct a comprehensive analysis and reverse
2722 engineering of the entire system. Instead, we will focus on specific parts
2723 for analysis. We leave it to the reader or those interested in utilizing the
2724 proposed methodology and framework to complete the analysis, should
2725 they choose to do so.

2726 By focusing on selective components and leaving room for further ex-
2727 ploration, we strike a balance between providing valuable insights and
2728 acknowledging the potential for additional research. This approach em-
2729 powers the reader and interested individuals to explore the iTrust SWaT
2730 system further and leverage the proposed methodology and framework
2731 for a more comprehensive analysis.

2732 6.1 Preliminary Operations

2733 Prior to beginning the actual analysis, several preliminary manual op-
2734 erations need to be conducted on the physical process dataset utilized as
2735 a case study, specifically the SWaT system dataset for the year 2015 as out-
2736 lined in Section 5.2.1. To simulate the data-capture process performed by
2737 Ceccato et al. using their scanning tool, the original dataset in XLSX format
2738 (proprietary to Microsoft Excel) was divided into multiple datasets in CSV
2739 format. Each of these datasets corresponds to the individual stages of the
2740 SWaT system and contains the respective registers. These resulting files
2741 were then saved in the directory specified by the `raw_dataset_directory`
2742 directive in the framework configuration file, `config.ini`, ready to be used
2743 in the pre-processing phase. Furthermore, the headers were manually re-
2744 named by adding a prefix from P1_ to P6_ to each register's name. This
2745 prefix indicates the stages, ensuring that each register is easily identifiable
2746 and linked to its corresponding stage.

2747 6.2 Planning the Analysis Strategy

2748 The complexity of the system being analyzed necessitates the adoption
2749 of a deliberate strategy for the analysis. It is not feasible to rely on trial and
2750 error or attempt every possible combination between stages. The former
2751 approach may overlook crucial relationships between PLCs or between
2752 registers, while the latter may result in excessive and unproductive efforts
2753 if the specific portion of the system being analyzed lacks significant infor-
2754 mation or relationships. A sound analysis strategy helps us focus on the
2755 important parts of the system, improving the quality of the analysis and
2756 leading to better process comprehension. By prioritizing our attention, we
2757 can gain a deeper understanding of the crucial components, resulting in
2758 more informed decision-making and a comprehensive understanding of
2759 the overall processes.

2760 To define this strategy, a potential starting point could involve analyz-

ing network traffic to determine the communication patterns and participants within the system. This can be accomplished by utilizing the techniques discussed in Section 4.2.2 on Network Analysis. By applying the Python script described in that section to the data extracted from the network traffic dataset debated in Section 5.2.1, we can generate a (simplified) network graph, as illustrated in Figure 6.1.

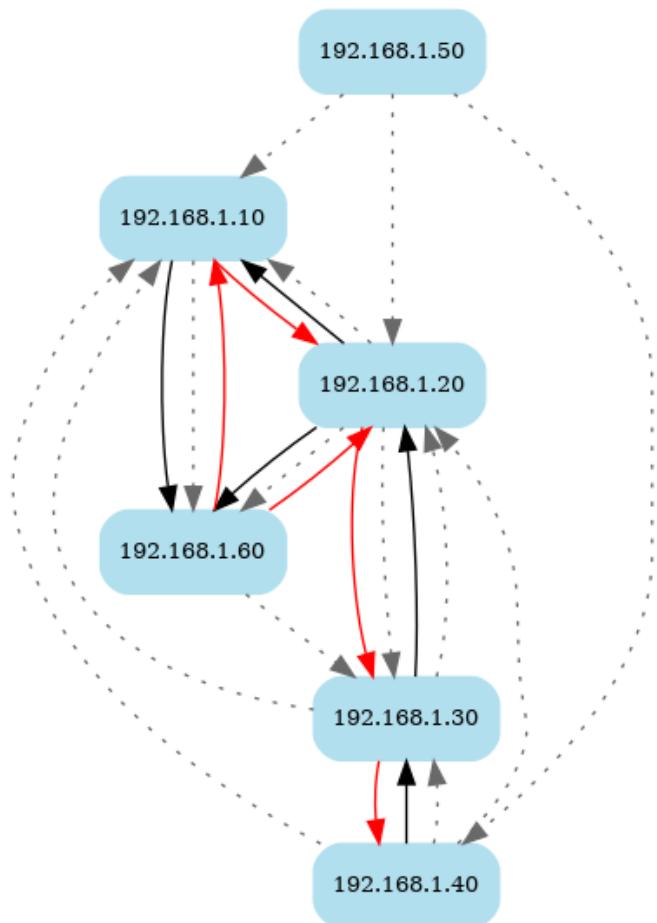

Figure 6.1: Simplified graph of the iTrust SWaT system network

The graph clearly illustrates the structure of communications between the PLCs. Referring back to Table 5.1, which displays the IP address - PLC associations, we can observe that PLCs 1 through 4 communicate directly and sequentially with each other in a Request/Response communication pattern (represented by red and black arrows, respectively). Additionally,

2772 PLC6 communicates with both PLC1 and PLC2. On the other hand, the
2773 gray dotted arrows indicate communications for which we have knowl-
2774 edge of a response, but the corresponding request is unknown. For the
2775 purposes of our analysis strategy, we will not consider these communica-
2776 tions within this context.

2777 Based on our observations, the analysis strategy we will adopt involves
2778 considering sequential pairs of PLCs to effectively capture the relation-
2779 ships and implications between registers. Therefore, the PLC pairs we
2780 will focus on are PLC1-2, PLC2-3, and PLC3-4.

2781 **6.3 Reverse Engineering of the iTrust SWaT Sys-
2782 tem**

2783 Before we delve into the analysis, it is important to provide some pre-
2784 liminary remarks.

2785 **Analysis structure** Firstly, the analysis will be structured as a schematic
2786 analysis due to space constraints, which prevent us from presenting the
2787 extensive inferences and reasoning regarding the system in full detail.
2788 However, the general procedure of the methodology and how to reason
2789 about the data obtained from the framework have already been demon-
2790 strated through examples on the PLC1 of the SWaT system in Chapter 4.
2791 We encourage readers to refer to those examples for a more comprehen-
2792 sive understanding. In this analysis, our focus will be on illustrating the
2793 conjectures and properties that arise from the analysis, utilizing tables and
2794 the outputs generated during the analysis.

2795 **Defining subsystem time duration** The second premise addresses the
2796 process of defining the subsystems to be analyzed, which were obtained
2797 during the pre-processing phase, during the merge phase of the individual
2798 datasets. Apart from the projection determined by the considered PLCs,

2799 a time-based selection of the analysis period has also been performed (see
2800 Section 4.2.3.1). This selection spans a duration of 20,000 seconds, which
2801 is equivalent to approximately five and a half hours or roughly five sys-
2802 tem cycles. The analysis begins at 100,000 seconds, which corresponds to
2803 approximately 27 hours from the start of the available data. This deliber-
2804 ate selection aims to exclude the initial transient period during which the
2805 SWaT system is initialized. We believe that this time range is more than
2806 sufficient for accurately defining the characteristics of the SWaT system
2807 components.

2808 **Conventions** The third premise introduces some conventions regarding
2809 the PLC registers that will be utilized during the analysis. These conven-
2810 tions aid in identifying the nature and function of the registers. Specifi-
2811 cally:

- 2812 1. Registers containing *discrete values*, such as binary or ternary values,
2813 are likely to represent **actuators**.
- 2814 2. Registers with *continuous values* are likely to represent **measurements**.
- 2815 3. Actuators with three states are recognized as **valves**, while those
2816 with two states are considered **pumps**. The definitions of *valve* and
2817 *pump* in this context are arbitrary and primarily serve the purpose of
2818 distinguishing between the two types of registers.
- 2819 4. Measurements that encompass a broader spectrum of values, fluctu-
2820 ating between maximum and minimum thresholds, are commonly
2821 designated as **level sensors** utilized for tank monitoring. Conversely,
2822 Measurements characterized by a narrower range may serve other
2823 measurement purposes, such as **flow or pressure sensing**.
- 2824 5. Registers with a single constant value are recognized as either **rela-**
2825 **tive setpoints** or **backup actuators**. The distinction is made based
2826 on the value contained in the register. Binary values or values corre-
2827 sponding to the states of the main actuators indicate backup actua-

2828 tors, while different values (e.g., 20, 40, 80, etc.) suggest the presence
2829 of relative setpoints.

2830 6. Registers with similar names, such as P1_LIT101 and P3_LIT301, or
2831 P2_MV201 and P3_MV302, indicate the same type of register, such as a
2832 valve, pump, level sensor, or other category.

2833 By following these conventions, it becomes easier to interpret and ana-
2834 lyze the functionality of the PLC registers within the system.

2835 **About the Business Process Analysis** In the end, the Business Process
2836 Analysis will focus solely on the physical process part. This is because the
2837 datasets of network traffic captures provided by iTrust for the year 2015
2838 (as discussed in Section 5.2.1) are **incomplete**. While communications re-
2839 lated to measurements are present, those associated with actuators are en-
2840 tirely missing, as well as additional communications related to other sys-
2841 tem characteristics that we observed in the datasets of subsequent years.
2842 As a result, we were unable to incorporate the network event recognition
2843 component into our Business Process Analysis. To implement this com-
2844 ponent, we would require complete and overlapping network data, along
2845 with a clean physical process dataset not affected by system attacks. Un-
2846 fortunately, none of the available iTrust datasets fulfill these criteria.

2847 6.3.1 Reverse Engineering of PLC1 and PLC2

2848 The initial focus of analysis will be on the pair comprising PLC1 and
2849 PLC2. Let's delve into the main features of this subsystem by examining
2850 the outcomes obtained from applying the framework to it.

2851 6.3.1.1 Pre-processing - Preliminary Analysis

2852 **Measurements and Actuators Recognition** Listing 6.1 shows the out-
2853 comes obtained from automatic recognition of likely measurements and
2854 actuators:

```

2855 1 Actuators:
2856 2 P1_MV101 [0.0, 1.0, 2.0]
2857 3 P1_P101 [1.0, 2.0]
2858 4 P2_MV201 [0.0, 1.0, 2.0]
2859 5 P2_P203 [1.0, 2.0]
2860 6 P2_P205 [1.0, 2.0]
2861 7
2862 8 Sensors:
2863 9 P1_FIT101 {'max_lvl': 2.7, 'min_lvl': 0.0}
2864 10 P1_LIT101 {'max_lvl': 815.1, 'min_lvl': 489.6}
2865 11 P2_AIT201 {'max_lvl': 256.5, 'min_lvl': 252.9}
2866 12 P2_AIT202 {'max_lvl': 8.4, 'min_lvl': 8.3}
2867 13 P2_AIT203 {'max_lvl': 342.8, 'min_lvl': 320.0}
2868 14 P2_FIT201 {'max_lvl': 2.5, 'min_lvl': 0.0}
2869 15
2870 16 Hardcoded setpoints or spare actuators:
2871 17 P1_P102 [1.0]
2872 18 P2_P201 [1.0]
2873 19 P2_P202 [1.0]
2874 20 P2_P204 [1.0]
2875 21 P2_P206 [1.0]

```

Listing 6.1: Preliminary analysis outcomes for sensors and actuators of PLC1–2

Based on the results shown in Listing 6.1, the framework has recognized P1_MV101, P1_P101, P2_MV201, P2_P203, and P2_P205 as **likely actuators**. The actuators indicated by the *Pxxx* string are binary actuators, meaning they have two states represented by the values 1 and 2. On the other hand, the actuators identified by the *MVxxx* string are ternary actuators with three distinct states: 0, 1, and 2. According to the third premise of Section 6.3, for point 3, actuators denoted by the *Pxxx* string will be classified as **pumps**, while those labeled with *MVxxx* will be recognized as **valves**.

P1_FIT101, P1_LIT101, P2_AIT201, P2_AIT202, P2_AIT203, and P2_FIT201 have been identified as **likely measurements**. Each measurement provides a specific range of values, spanning from a maximum to a minimum value. Based on the range of values reported by these measurements and

according to the third premise of Section 6.3, for point 4, it is reasonable to infer that P1_LIT101 could potentially be a **level sensor for a tank**.

In addition, there are some registers that have been recognized as **hard-coded setpoints or spare actuators** due to their constant values. These registers share a resemblance to the previously identified pump registers. According to points 5 and 6 of the third premise in Section 6.3, it is reasonable to assume that these registers correspond to **spare actuators**. Furthermore, the fact that they have a constant value of 1 indicates that they might represent the **OFF state** of the pumps.

Actuator State Durations To gain a deeper understanding of the different states (0, 1, and 2) associated with valves P1_MV101 and P2_MV201, we can analyze the duration of each state. Listing 6.2 provides information regarding the duration (in seconds) of states for these specific actuators:

```

2902 1 Actuator state durations:
2903 2 P1_MV101 == 0.0
2904 3 9 9 10 9 9 10 9 9 10 9
2905 4
2906 5 P1_MV101 == 1.0
2907 6 1174 1168 1182 1160 1172
2908 7
2909 8 P1_MV101 == 2.0
2910 9 669 3019 3012 3000 2981
2911 10
2912 11 P2_MV201 == 0.0
2913 12 8 8 8 9 9 8 9 9 9 9
2914 13
2915 14 P2_MV201 == 1.0
2916 15 1057 1057 1045 1038 1039
2917 16
2918 17 P2_MV201 == 2.0
2919 18 120 3135 3144 3127 3109

```

Listing 6.2: Time duration of the states of actuators P1_MV101 and P1_MV201 of PLC1-2

It is evident that the duration of **state 0 is relatively short**, averaging

2921 around 8-10 seconds, while the other states have much longer durations.
 2922 This observation suggests that state 0 of a valve is a **transient state**, in-
 2923 dicating a transitional phase within the valve cycle. However, without
 2924 further information, it is currently not possible to determine the specific
 2925 position of state 0 within the overall valve cycle.

2926 **Actuator State Changes** Now that we have identified P1_LIT101 as the
 2927 supposed tank, we can examine the trend of the tank level as the actuators
 2928 change state. Listing 6.3 provides information on the levels of the tank in
 2929 correlation with the state changes of the P1_P101 pump:

| | | | | |
|------|----|-----------|---------|--------------|
| 2930 | 1 | P1_LIT101 | P1_P101 | prev_P1_P101 |
| 2931 | 2 | 536.0356 | 1 | 2 |
| 2932 | 3 | 533.3272 | 1 | 2 |
| 2933 | 4 | 542.1591 | 1 | 2 |
| 2934 | 5 | 534.8581 | 1 | 2 |
| 2935 | 6 | 540.5890 | 1 | 2 |
| 2936 | 7 | | | |
| 2937 | 8 | P1_LIT101 | P1_P101 | prev_P1_P101 |
| 2938 | 9 | 813.0031 | 2 | 1 |
| 2939 | 10 | 813.0031 | 2 | 1 |
| 2940 | 11 | 811.8256 | 2 | 1 |
| 2941 | 12 | 812.7283 | 2 | 1 |
| 2942 | 13 | 813.3171 | 2 | 1 |

Listing 6.3: P1_P101 state changes in relation to P1_LIT101

2943 Based on the speculation that state 1 represents the OFF state of the
 2944 pump and state 2 represents the ON state, we can analyze the data in List-
 2945 ing 6.3. When pump P1_P101 transitions from the ON state to the OFF
 2946 state, the average level of P1_LIT101 is 535. On the other hand, when
 2947 P1_P101 goes from the OFF state to the ON state, the average level of
 2948 P1_LIT101 is 813. These values correspond to the **minimum and maxi-**
 2949 **mum relative setpoints** of P1_P101, respectively.

2950 Based on this information, we can infer that pump P1_P101 is respon-
 2951 sible for **emptying the tank**. Moreover, it can be extended to assume that
 2952 a pump, in general, is responsible for **water outflow**.

2953 Applying the same analysis to the data for valve P1_MV101, which is not
2954 reported for conciseness, we can speculate that P1_MV101 is responsible for
2955 **filling the tank**. In this case, states 1 and 2 would represent the **OFF and**
2956 **ON states of the valve**, respectively. The relative setpoints of P1_MV101
2957 are approximately 500 (minimum) and 800 (maximum). By extending this
2958 analysis, we can speculate that a valve, such as P1_MV101, is responsible
2959 for controlling the **water inflow**.

2960 Regarding the elements controlled by PLC2 and the sensor P1_FIT101,
2961 the analysis does not reveal the presence of another tank. Therefore, we
2962 cannot determine the exact role of sensors P2_AIT20x, P1_FIT101 and P2_FIT201
2963 at this point. However, there is a similarity observed between the relative
2964 setpoints of P1_P101 and those of P2_MV201, P2_P203, and P2_P205. These
2965 registers exhibit very similar values during state changes, suggesting a
2966 potential relationship or similar control behavior between them.

2967 6.3.1.2 Graphs and Statistical Analysis

2968 Figure 6.2 illustrates the graphical representation of the registers in
2969 PLC1-2 and their respective trends.

2970 The image provides additional support to the conjectures made during
2971 the preliminary analysis regarding the spare actuators. Furthermore, it is
2972 evident from the graphs that these spare actuators **do not appear to influ-**
2973 **ence the trend** of any of the measurements. Therefore, based on this obser-
2974 vation, we can confidently exclude these registers from further graphical
2975 analysis.

2976 Figure 6.3 shows a clearer representation of the subsystem after remov-
2977 ing the spare actuators.

2978 Figure provides furthermore additional insights that allow us to spec-
2979 ulate on aspects that remained unexplained during the preliminary analy-
2980 sis. The most prominent aspect that stands out is the relationship between
2981 the level behavior of P1_LIT101 and the states of P1_P101 and P1_MV101. It
2982 becomes evident that these two actuators **are not mutually exclusive**, and

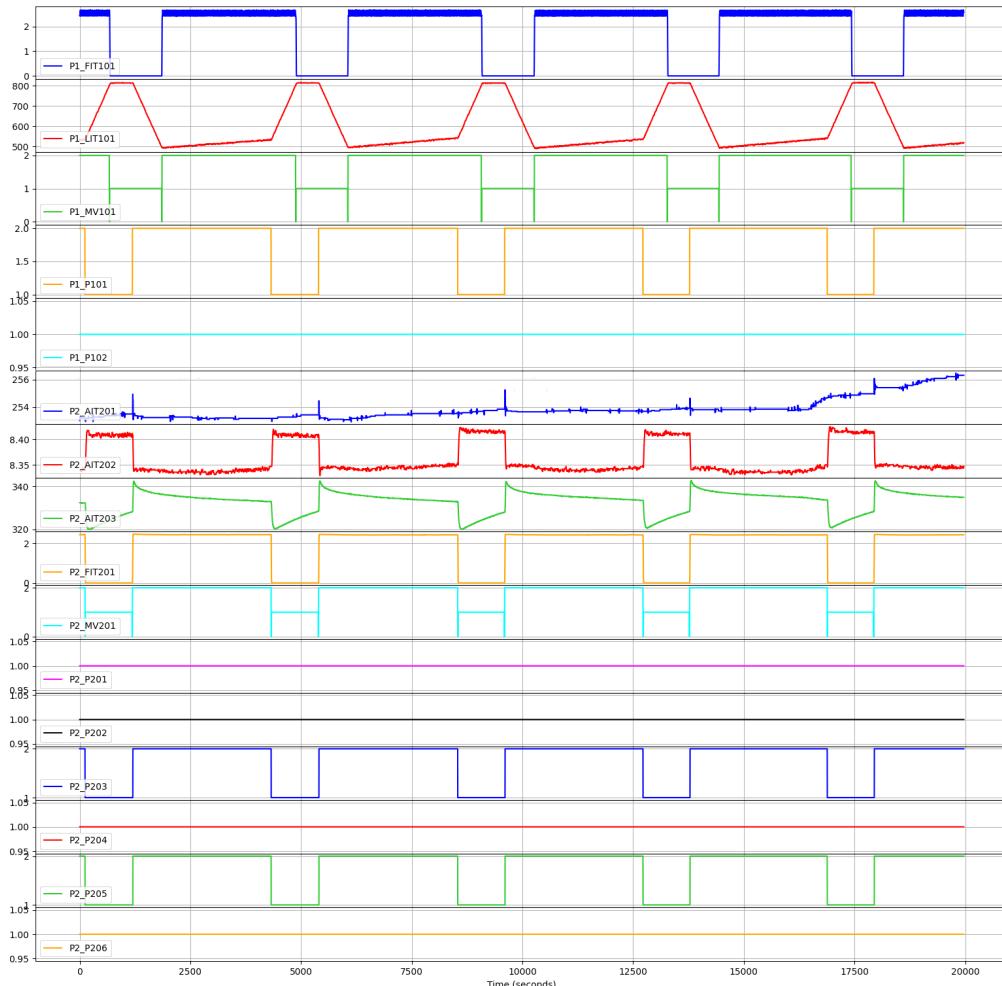

Figure 6.2: Chart of PLC1-2 registers

2983 when they are both in the ON state, the growth of the tank level is slow.
 2984 However, as soon as P1_P101 switches to the OFF state, the tank level
 2985 starts to increase at a faster rate. Conversely, when P1_MV101 switches to
 2986 the OFF state, the tank level decreases. During periods when both actu-
 2987 ators are in the OFF state, there is a *plateau* where the tank level remains
 2988 relatively stable.

2989 Furthermore, we observe a relationship between P1_FIT101 and the
 2990 trend of P1_MV101. When the valve is in the off state, P1_FIT101 registers
 2991 a value of 0, whereas it registers a value greater than 2 when the valve is

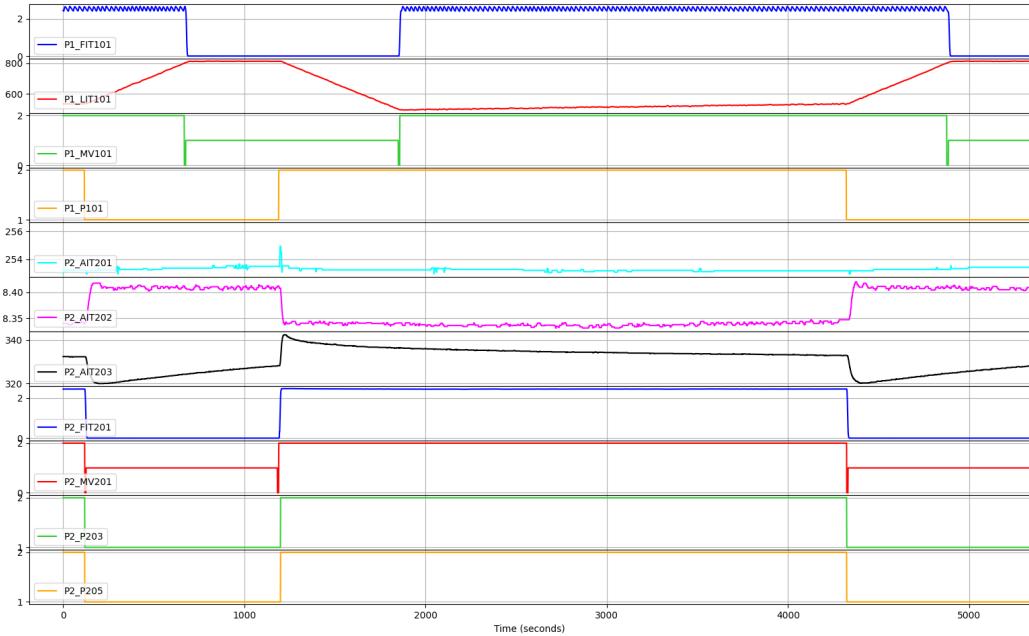

Figure 6.3: Chart of PLC1-2 registers without spare actuators (particular)

2992 open. This suggests that P1_FIT101 could be a **sensor associated with the**
 2993 **flow** of water entering the tank, which is represented by P1_LIT101. By
 2994 drawing an analogy with its name, it is plausible to consider P2_FIT201 as
 2995 another flow sensor.

2996 Another intriguing aspect that arises from examining the graphs in Figure
 2997 6.2 and Figure 6.3 is the **non-cyclic pattern** observed in the P2_AIT201
 2998 measurement. Instead of exhibiting a cyclical trend, it follows a linear
 2999 pattern. Furthermore, considering the narrow range of values associated
 3000 with this measurement, it is reasonable to speculate that P2_AIT201 may be
 3001 associated with a **sensor that measures a specific property of the water**.

3002 The limited range of values observed in P2_AIT202 also raises the pos-
 3003 sibility that it functions as a sensor for a particular water characteristic,
 3004 despite exhibiting a cyclic pattern. As for P2_AIT203, its role remains un-
 3005 defined, although it also displays a cyclic trend. This trend, along with that
 3006 of P2_AIT202, does not appear to be related to the behavior of the valves
 3007 (which rules out the possibility of it being related to a tank), but rather

3008 to that of the pumps. Consequently, it is imperative to conduct further
3009 investigations into these aspects.

3010 By examining the trend of valve P2_MV201, an additional speculation
3011 can be made. It appears to be independent of the trends observed in any
3012 of the measurements within this subsystem. Based on previous conjectures
3013 regarding the role of valves and considering the duration of its ON
3014 and OFF states, it is possible that P2_MV201 is responsible for **filling a tank**
3015 **that is not part of this particular subsystem**. Once again, a thorough investigation
3016 is necessary to confirm this hypothesis.

3017 **6.3.1.3 Invariant Inference and Analysis**

3018 Through the process of *invariant analysis*, we aim to discover new information
3019 about the system and determine whether the conjectures made
3020 in the previous steps are supported by the data obtained from the Daikon
3021 analysis.

3022 **General Invariants** We will begin this phase by analyzing the general
3023 invariants (see Section 4.2.5.1.). Listing 6.4 presents a selection of these
3024 invariants:

```
3025 1 P2_P206 == P2_P204 == P2_P202 == P2_P201 == P1_P102 == 1.0
  2 P2_P205 == P2_P203
  3 max_P1_LIT101 == 816.0
  4 min_P1_LIT101 == 489.0
  5 max_P2_AIT201 == 257.0
  6 min_P2_AIT201 == 252.0
  7 max_P2_AIT202 == 9.0
  8 min_P2_AIT202 == 8.0
  9 max_P2_AIT203 == 343.0
 10 min_P2_AIT203 == 320.0
```

Listing 6.4: General Invariants for PLC1-2

3035 The invariant mentioned on line 2 is particularly significant: it states
3036 that P2_P203 and P2_P205 always have the same values. While this information
3037 was somewhat apparent in the previous steps, it becomes more

3038 apparent and evident in this analysis. This observation leads us to speculate
 3039 that the two pumps, P2_P203 and P2_P205, **are related to each other** in
 3040 some way. The other invariants provided in this section further reinforce
 3041 the hypotheses about the spare actuators.

3042 **Analysis on Single Actuator States** We proceed with the examination
 3043 of the invariants derived from the *first of the two semi-automatic analysis*
 3044 discussed in Section 4.2.5.2. Specifically, we will focus on the analysis con-
 3045 cerning the states of individual actuators in relation to a specific measure-
 3046 ment, which in our case pertains to the tank represented by P1_LIT101. For
 3047 illustrative purposes, let's consider states 1 and 2 (OFF e ON respectively)
 3048 of valve P1_MV101 as an example (we will disregard state 0 as it is consid-
 3049 ered transient). The conditional invariants pertinent to this scenario can
 3050 be found in Listing 6.5.

```

3051   1 =====
3052   2 P1_MV101 == 1.0 && P1_LIT101 < max_P1_LIT101 - 16 &&
3053     ↪ P1_LIT101 > min_P1_LIT101 + 15
3054   3 =====
3055   4 ...
3056   5 P2_P205 == P2_P203 == P2_MV201 == P1_P101 == 2.0
3057   6 P1_FIT101 == 0.0
3058   7 slope_P1_LIT101 == -1.0
3059   8 P2_FIT201 > P1_FIT101
3060   9 P2_FIT201 > P1_MV101
3061  10 P2_FIT201 > P1_P101
3062  11 ...
3063  12
3064  13 =====
3065  14 P1_MV101 == 2.0 && P1_LIT101 < max_P1_LIT101 - 16 &&
3066     ↪ P1_LIT101 > min_P1_LIT101 + 15
3067  15 =====
3068  16 slope_P1_LIT101 == P1_P102
3069  17 P1_FIT101 > P1_MV101
3070  18 ...
3071  19 P1_MV101 >= P1_P101
3072  20 P1_MV101 >= P2_MV201

```

```
3073 21 P1_MV101 >= P2_P203  
3074 22 P2_P203 >= P1_P101  
3075 23 . . .
```

Listing 6.5: Conditional Invariants for states 1 and 2 of P1_MV101

3076 To prevent transient periods caused by water flow stabilization when
3077 the actuators change state, a condition is imposed on the level of P1_LIT101.
3078 However, this condition may result in an incomplete understanding of the
3079 system's behavior. To address this, a manual refinement of the analysis is
3080 required, utilizing the `runDaikon.py` script as outlined in Section 4.2.5.2.

3081 Based on the analysis, the following observations can be made when
3082 the valve is in the OFF state:

- 3083 • The slope of P1_LIT101, denoted as `slope_P1_LIT101`, is negative
3084 (line 7). This indicates a **downward trend** in the tank level, as we
3085 have seen in Section 6.3.1.1.
- 3086 • P1_P101 is in state 2, or ON (line 5).
- 3087 • P1_FIT101 is zero (line 6).
- 3088 • P2_FIT201 has a value greater than 2 (line 10).

3089 On the other hand, when the valve is in the ON state:

- 3090 • `slope_P1_LIT101` is positive (line 16). This indicates an **upward trend**
3091 in the tank level, as we have seen in Section 6.3.1.1.
- 3092 • P1_FIT101 assumes a value greater than 2. The combination of this
3093 finding, along with the previous one regarding the same register,
3094 strengthens the hypothesis that this is indeed a flow sensor.
- 3095 • P1_P101 can be in either the ON or OFF state, as we have seen in
3096 Section 6.3.2.2.

3097 When conducting a manual analysis using the `runDaikon.py` script on
 3098 tank levels that fall outside the range defined by the previous condition, it
 3099 does not yield useful slope information. This situation can occur because,
 3100 despite the noise attenuation applied to the tank level sensor data, if there
 3101 is even a single cycle in the system where the calculated slope deviates
 3102 from the expected outcome, it can adversely affect the entire Daikon anal-
 3103 ysis. Figure 6.4 shows this behavior.

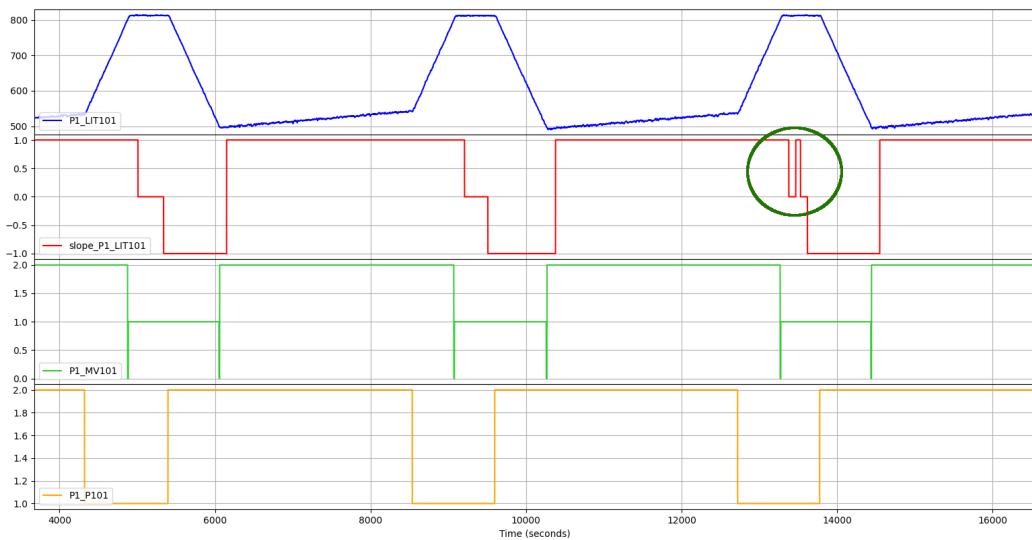

Figure 6.4: Slope calculation anomaly (in the circle)

3104 **Analysis of the Current System Configuration** We conclude our analy-
 3105 sis of invariants by considering the *second semi-automatic analysis* outlined
 3106 in Section 4.2.5.2, which focuses on the effective states of the system. Due
 3107 to the comprehensive nature of this analysis, we will not provide a de-
 3108 tailed report of the outputs to maintain brevity. However, this analy-
 3109 sis confirms the findings observed in the analysis of individual actuator
 3110 states. Additionally, one crucial piece of information becomes apparent
 3111 for future steps: the changing state of the actuators controlled by PLC2 **do**
 3112 **not impact the behavior of the tank** controlled by PLC1. Indeed, it is suf-
 3113 ficient to examine the invariant pertaining to the slope of the tank to verify
 3114 this observation.

3115 6.3.1.4 Business Process Mining and Analysis

3116 As explained in Section 4.2.6.1, the *process mining phase* applied to the
3117 physical system provides us with an immediate understanding of the sys-
3118 tem cycle and the chronological sequence of states. It enables us to de-
3119 termine the duration of time the system remains in a particular state and
3120 at what relative setpoint the state transition occurs concerning the refer-
3121 ence measure. Furthermore, we can analyze the trend of this measure
3122 within each state. Additionally, we can examine the relative setpoints of
3123 other measurements to identify any connections between changes in sys-
3124 tem state and these values.

3125 Given that we have already identified the likely measurement repre-
3126 senting the tank and the corresponding actuators that control its behavior,
3127 an activity diagram can be generated as depicted in Figure 6.5.

3128 The activity diagram allows for easy interpretation of the tank level
3129 trend and slope within different states. The states where the valve has a
3130 value of 0 can be disregarded due to their short duration. Similar to the
3131 graphical analysis, there is an observed change in slope during the increas-
3132 ing trend of the tank level between the states $[P1_MV101 == 2, P1_P101 == 2]$ and $[P1_MV101 == 2, P1_P101 == 1]$, where the slope changes from
3133 0.02 to 0.48.
3134

3135 Additionally, the timing analysis on the edges reveals that the tank
3136 takes longer to fill than to empty, and the system remains in the $[P1_MV101 == 1, P1_P101 == 1]$ state for approximately 8 minutes (509 seconds).

3138 Regarding the state $[P1_MV101 == 1, P1_P101 == 1]$, there appears
3139 to be a discrepancy between the trend of the tank level as reported in the
3140 activity diagram and the conjectures made in the previous phases of the
3141 analysis. The activity diagram correctly depicts an increasing trend in the
3142 tank level between the end of the state $[P1_MV101 == 2, P1_P101 == 1]$ and the end of the state $[P1_MV101 == 1, P1_P101 == 1]$. However, the
3143 discrepancy arises due to the fact that the interruption of flow during the
3144 valve state change from state ON to state OFF is not immediate, mainly
3145

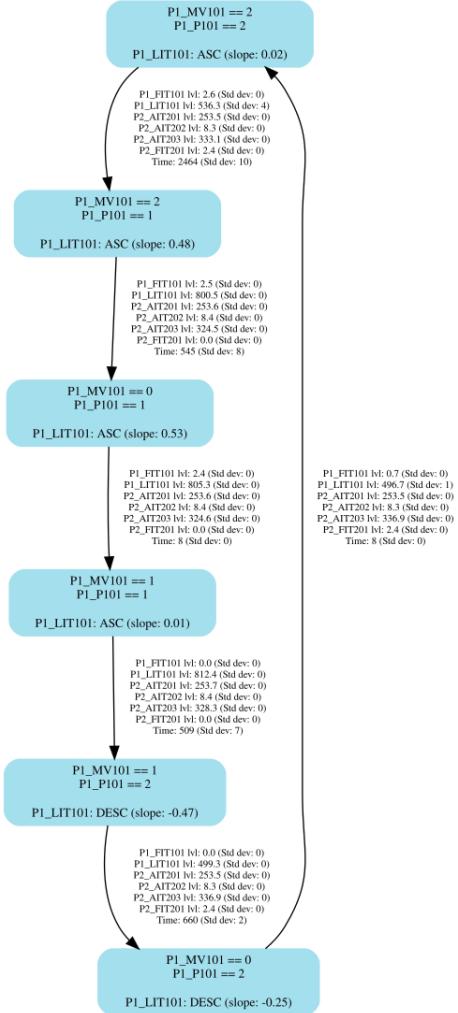

Figure 6.5: Activity diagram for PLC1-2

due to the presence of the transient state 0. Additionally, water continues to flow within the piping towards the tank for a short duration even after the valve is closed. After this period, which usually lasts a few seconds, the tank level stabilizes, and there is no further inflow or outflow of water.

By adjusting the tolerance parameter $-t$ in the processMining.py script, it is possible to obtain accurate data regarding the behavior of the state corresponding to the *plateau* observed in the graphical analysis.

The data presented on the arcs in the activity diagram represents the

3154 measurement values relative to the time of system state changes, specifically
3155 the relative setpoints. These values are calculated based on the average data collected in each cycle. By analyzing this data, we can observe
3156 the tank level values at which the system undergoes configuration changes
3157 and how the trend of the tank level changes accordingly. Specifically, we
3158 can see that the trend transitions from ascending to stable at a tank level
3159 value of 800, from stable to descending at approximately 812, and from
3160 descending back to ascending at around 499. The change in the speed of
3161 tank filling occurs at approximately 535.

3163 Furthermore, the data provides additional support for the hypothesis
3164 that the measurements associated with registers P2_AIT20x are not influ-
3165 enced by the tank's trends.

3166 **6.3.1.5 Properties**

3167 From the conjectures derived from the four phases of the analysis we
3168 will derive the properties of the subsystem we are studying, which will be
3169 placed within a **summary table**. This table contains an integer identifying
3170 the property, the statement of the property itself, and from which of the
3171 four phases it was derived.

| # | Statement | Derived from |
|----|--|--|
| P1 | The registers P1_LIT101, P1_FIT101, P2_AIT201, P2_AIT202, P2_AIT203, and P2_FIT201 are considered measurements. | Preliminary Analysis Graphical Analysis |
| P2 | The registers P1_MV101, P1_P101, P2_MV201, P2_P203, and P2_P205 are considered actuators. | Preliminary Analysis Graphical Analysis |
| P3 | The actuators that contain the substring "MVxxx" are considered to be three-state actuators. For simplicity, we refer to them as valves. | Preliminary Analysis |
| P4 | The state 0 of these valves represents a transient state that occurs during the transition between state 1 (OFF) and state 2 (ON). | Preliminary Analysis Graphical Analysis |

| | | |
|-----|---|--|
| P5 | The actuators that contain the substring "Pxxx" are considered to be binary actuators. For simplicity, we refer to them as pumps. | Preliminary Analysis |
| P6 | The registers P1_P102, P2_P201, P2_P202, P2_P204, and P2_P206 are considered spare actuators. They do <i>not</i> influence the trend of any measurements and they are considered in the OFF state. | Preliminary Analysis Graphical Analysis Invariant Analysis |
| P7 | P1_LIT101 represents the level sensor of the tank controlled by PLC1. | Preliminary Analysis Graphical Analysis |
| P8 | P1_MV101 and P1_P101 are the actuators responsible for the level behavior of the water contained in the tank. | Graphical Analysis Invariant Analysis Business Process |
| P9 | P1_MV101 is responsible for filling the tank. P1_P101 is responsible for emptying the tank. | Graphical Analysis Invariant Analysis |
| P10 | Valve are responsible for water inflow. Pumps responsible for water outflow. | Preliminary Analysis Graphical Analysis Invariant Analysis |
| P11 | The rate of tank level growth is slow when both P1_MV101 and P1_P101 are in the ON state. The growth speed increases when P1_P101 transitions to the OFF state. | Graphical Analysis Business Process |
| P12 | The tank level decreases when P1_MV101 is in the OFF state and P1_P101 is in the ON state. | Graphical Analysis Invariant Analysis |
| P13 | The tank level remains (relatively) stable when both P1_MV101 and P1_P101 are in the OFF state. | Graphical Analysis Business Process |
| P14 | The trend of the tank level transitions from ascending to stable when the level reaches approximately 800. It shifts from stable to descending when the level averages around 812. It changes from descending back to ascending when the level reaches about 500. The speed of tank filling increases noticeably at around 535. | Business Process |
| P15 | Absolute setpoints are 800, 812, 500 and 535. | Business Process |
| P16 | P1_FIT101 serves as a flow sensor to measure the inflow of water into the tank. | Graphical Analysis Invariant Analysis Business Process |

| | | |
|-----|---|--|
| P17 | None of the actuators connected to PLC2 have an impact on the level of the tank controlled by PLC1. | Graphical Analysis Invariant Analysis Business Process |
| P18 | None of the measurements connected to PLC2 represent a tank. | Preliminary Analysis Graphical Analysis |
| P19 | P2_AIT201 does not exhibit a cyclic trend. | Graphical Analysis |
| P20 | Both P2_AIT201 and P2_AIT202 serve as sensors for measuring certain properties of the water. | Preliminary Analysis Graphical Analysis |
| P21 | The behavior and trend of P2_AIT202 and P2_AIT203 are directly associated with the operation of the pump. | Graphical Analysis Invariant Analysis |

Conclusion and Future Work

3182 **Discussion** Upon completing our black-box analysis of the iTrust SWaT
3183 system, although partial, we can confidently state that we have achieved a
3184 significant level of process comprehension for the examined system. Fur-
3185 thermore, we have successfully derived a relatively accurate model of its
3186 behavior. Specifically:

- 3187 1. we successfully identified the registers associated with the physical
3188 process measures and their respective operating ranges (setpoints);
- 3189 2. among these measurements, we were able to distinguish the sensors
3190 responsible for monitoring the water level in the tanks;
- 3191 3. we identified the registers associated with the actuators, such as pumps
3192 and valves, and determined their ON and OFF states;
- 3193 4. we were able to determine whether an actuator is responsible for
3194 controlling incoming or outgoing flows within the system;
- 3195 5. we successfully identified the possible states that the system may
3196 assume and determined the chronological sequence in which these
3197 states occur;
- 3198 6. we recognized the specific events that trigger changes in the system
3199 state through the actuators, such as reaching specific water level val-
3200 ues in the tanks, and vice versa;

- 3201 7. we elucidated the relationships between registers belonging to dif-
3202 ferent PLCs, highlighting their interconnections and dependencies;
- 3203 8. we partially reconstructed the communication network between the
3204 PLCs, outlining the connections and interactions between them.

3205 For some registers it was not possible to derive their specific role (e.g.,
3206 register P2_AIT203 monitored by PLC2). In such cases, we were restricted
3207 to making conjectures or relying on generic properties inferred from other
3208 aspects. Additionally, based on the available data, we were unable to es-
3209 tablish the presence of piping or other elements such as filter membranes
3210 or tanks containing chemicals.

3211 Items 4, 5, and 8 in the aforementioned list highlight the expanded
3212 scope of information that can be obtained from the proposed framework
3213 compared to the work of Ceccato et al. Furthermore, the increased quan-
3214 tity and depth of information acquired at each step of the methodology
3215 reinforce our belief that the primary objective of this thesis has been fully
3216 accomplished.

3217 **Future work** Undoubtedly, the proposed framework can be further im-
3218 proved. Throughout the development of this thesis, ideas for potential
3219 enhancements have emerged, representing a natural evolution of the cur-
3220 rent proposal. In the following, we will illustrate these areas for future
3221 work:

- 3222 • **Scanning of the system and data gathering:** In our methodology,
3223 we excluded a particular step since we utilized the datasets pro-
3224 vided by iTrust, encompassing both physical process and network
3225 traffic data (for more details, please refer to Section 5.2). However,
3226 in cases where ready-made datasets are unavailable, this step may
3227 be necessary. It is important to note that the main limitation of this
3228 step, compared to the Ceccato et al. tool, is its exclusive focus on the

3229 recognition of PLCs based on the Modbus protocol. As we have ob-
3230 served, there exist numerous industrial protocols, and Modbus, al-
3231 though widely used, is just one among many. Therefore, it becomes
3232 imperative to ensure that this phase can effectively handle the recog-
3233 nition of PLCs using multiple protocols. To address this challenge,
3234 one can leverage the protocols directive within the [NETWORK] sec-
3235 tion of the general configuration file, *config.ini*.

3236 Another potential solution we propose is the implementation of an
3237 automatic recognition method utilizing Machine Learning and Arti-
3238 ficial Intelligence techniques. This approach has been explored and
3239 tested on the datasets related to the physical process of the SWaT
3240 system provided by iTrust. Unfortunately, these datasets proved to
3241 be inconsistent in many instances, which hindered the adequacy of
3242 training. As a result, this avenue was abandoned. However, if an
3243 attacker has the capability to conduct repeated series of scans on the
3244 target system, they could utilize this data collection to train a model
3245 for recognition purposes;

- 3246 • **Automatic recognition of measurements and actuators:** this aspect
3247 was implemented within our framework using a mixed Daikon-Pandas
3248 technique. While this technique has shown positive results, it can be
3249 further improved by modifying it to utilize only the Pandas library.
3250 The revised technique would involve checking the type and num-
3251 ber of distinct values in each register to accurately identify measure-
3252 ments and actuators. This modification would offer greater flexibil-
3253 ity and precision in the recognition process, allowing for the defini-
3254 tion of specific criteria, such as setting a maximum number of dis-
3255 tinct values to determine whether a register should be classified as
3256 an actuator;
- 3257 • **Completion of Business Process Analysis and Network Analysis:**
3258 in our implementation, these aspects remained incomplete, as stated
3259 in Section 6.3, due to the unavailability of comprehensive and over-

3260 lapping data in the datasets provided by iTrust for the given years.
3261 To address this, improvements are required, such as enhancing the
3262 multiprotocol support of the network data export script (currently
3263 adapted to CIP only) and suggesting a modular solution. Addition-
3264 ally, it is necessary to implement an event recognition mechanism to
3265 identify system state changes within network communications;

- 3266 • **Recognition of actual system states:** in the steps related to Invariant
3267 Analysis and Business Process, it was necessary to manually specify
3268 the actuators that directly impact the subsystem under study, omit-
3269 ting the remaining ones. This approach allowed us to obtain the ac-
3270 tual states of the subsystem, enabling the derivation of information
3271 that is more immediate and likely more accurate. Throughout the
3272 thesis development, various methods were explored, including ap-
3273 proximating tank level data (similar to the approach used for slope
3274 calculation in Section 4.2.3.2) and identifying points of slope change.
3275 However, none of these methods proved effective due to significant
3276 data perturbations. Consequently, addressing this issue remains an
3277 ongoing challenge that requires additional time to find a consistent
3278 and reliable solution.

| 2.8 | Example of packet sniffing on the Modbus protocol | 21 |
| 2.9 | OSI model for EtherNet/IP stack | 22 |
| 3.1 | Workflow of Ceccato et al.'s stages and operations with used tools | 30 |
| 3.2 | The simplified SWaT system used for running Ceccato et al. methodology | 31 |
| 3.3 | Output graphs from graph analysis | 35 |
| 3.4 | An example of Disco generated activity diagram for PLC2 . | 39 |
| 3.5 | Execution traces of InputRegisters_IW0 on the three PLCs . | 41 |
| 3.6 | Business process with states and Modbus commands for the three PLCs | 43 |
| 3.7 | Water physics compared: simulated physics in the Simulink model (a) and physics in a real system (iTrust SWaT) (b). Fluctuations in the tank level in (b), almost completely absent in (a), can be appreciated. | 49 |

| | | |
|------|---|-----|
| 3.8 | Behavior of the Graph Analysis on the Ceccato et al.'s tool | 51 |
| 3.9 | Histogram plot overshadowing statistical information shown on the terminal window in the background | 52 |
| 3.10 | Example of Daikon's output | 54 |
| 4.1 | Network Communications between 192.168.1.40 (Source) and 192.168.1.30 (Destination) | 70 |
| 4.2 | Network Communications between 192.168.1.40 (Source) and 192.168.1.30 (Destination) in textual mode | 71 |
| 4.3 | Slope comparison with granularity 30 (a), 60 (b) and 120 seconds (c) | 79 |
| 4.4 | Savitzky-Golay filter (blue line), STL decomposition (green) and RDP algorithm (orange) comparison | 81 |
| 4.5 | Slope after the application of the STL decomposition | 82 |
| 4.6 | The new slope representation (green line) and the smoothed measurement data obtaind with the STL decomposition (red) | 83 |
| 4.7 | Plotting registers on the same y-axis | 87 |
| 4.8 | Example of the new graph analysis | 88 |
| 4.8 | Example of the new graph analysis (cont.) | 89 |
| 4.9 | Example of transitive closure graphs for invariants in PLC1 of iTrust SWaT system | 93 |
| 4.10 | Directory (a) and outcome files (b) for the single actuator states analysis | 97 |
| 4.11 | Daikon outcome files for system configuration analysis. Each file represents a single system state | 97 |
| 4.12 | Activity diagram for PLC1 of the iTrust SWaT system | 104 |
| 5.1 | SWaT architecture | 109 |
| 5.2 | Sensors and actuators associated with each PLC | 110 |
| 5.3 | SWaT network architecture | 111 |
| 5.4 | SWaT stabilization | 114 |
| 6.1 | Simplified graph of the iTrust SWaT system network | 119 |
| 6.2 | Chart of PLC1-2 registers | 127 |

| | | |
|-----|--|-----|
| 6.3 | Chart of PLC1-2 registers without spare actuators (particular) | 128 |
| 6.4 | Slope calculation anomaly (in the circle) | 132 |
| 6.5 | Activity diagram for PLC1-2 | 134 |

List of Tables

| | | |
|-----|---|-----|
| 2.1 | differences between Information Technology (IT) and Industrial Control Systems (ICSs) | 6 |
| 2.2 | Modbus Function Codes list | 20 |
| 3.1 | Summary table of Ceccato et al. framework limitations | 56 |
| 5.1 | main IP addresses of the six PLCs and SCADA in SWaT | 112 |
| 5.2 | SWaT network traffic data | 115 |
| 6.1 | Properties of the PLC1-2 subsystem | 137 |

Listings

| | | |
|-----|---|-----|
| 3.1 | Example of registers capture | 33 |
| 3.2 | Example of raw network capture | 34 |
| 3.3 | Statistical data for PLC1_InputRegisters_IW0 register | 36 |
| 3.4 | Generic example of a .spinfo file for customizing rules in Daikon | 37 |
| 3.5 | The three sections of Daikon analysis outcomes | 37 |
| 4.1 | Novel Framework structure and Python scripts | 61 |
| 4.2 | Paths and parameters for the Pre-processing phase in <i>config.ini</i> file | 73 |
| 4.3 | config.ini parameters for dataset enriching | 75 |
| 4.4 | Example of preliminary system analysis | 84 |
| 4.5 | Standard Daikon output for PLC1 of the iTrust SWaT system | 91 |
| 4.6 | Revised Daikon output with transitive closures for PLC1 of the iTrust SWaT system | 94 |
| 4.7 | Daikon outcomes for the system configuration MV101 == 2, P101 == 1 on LIT101 | 98 |
| 4.8 | Example of the data contained in the produced JSON file | 102 |
| 6.1 | Preliminary analysis outcomes for sensors and actuators of PLC1-2 | 123 |
| 6.2 | Time duration of the states of actuators P1_MV101 and P1_MV201 of PLC1-2 | 124 |
| 6.3 | P1_P101 state changes in relation to P1_LIT101 | 125 |
| 6.4 | General Invariants for PLC1-2 | 129 |

6.5 Conditional Invariants for states 1 and 2 of P1_MV101 130
